Higher-Order Rewrite Systems and their Confluence

Richard Mayr & Tobias Nipkow*
TU München†

Abstract

We study Higher-Order Rewrite Systems (HRSs) which extend term rewriting to λ-terms. HRSs can describe computations over terms with bound variables. We show that rewriting with HRSs is closely related to undirected equational reasoning. We define Pattern Rewrite Systems (PRSs) as a special case of HRSs and extend three confluence results from term rewriting to PRSs: the critical pair lemma by Knuth and Bendix, confluence of rewriting modulo equations *à la* Huet, and confluence of orthogonal PRSs.

1 Introduction

Much effort has gone into the study of first-order rewrite systems and as a result there is a large body of knowledge about their properties. In 1972, Knuth and Bendix published their seminal paper [19] which shows that confluence of terminating term-rewriting systems is decidable: a simple test of confluence for the finite set of so called critical pairs suffices. Later Huet [11] gave the definitive formulation of this result and extended it in several directions, including confluence for term-rewriting modulo certain equational theories.

The objective of this paper is to generalize some of these results from first-order rewrite systems (usually referred to as term-rewriting systems), where all functions are first-order, to rewrite systems over simply typed λ-terms. The aim of this generalization is to lift the rich theory developed around first-order rewrite systems and apply it to systems manipulating higher-order terms, such as program transformers, theorem provers and the like. In particular, this paper can be seen as an investigation of (a fragment of) the meta-theory of theorem provers like HOL [9] and Isabelle [33]: both systems are based on the simply typed λ-terms and their logic contains equality. On a more practical level, the study of higher-order rewriting has lead to the development of a new and improved unification algorithm for a certain subclass of λ-terms [26], which is now part of Isabelle. Isabelle's rewrite engine is based completely on a particular form of higher-order rewriting, namely the Pattern Rewrite Systems introduced below, which is an extremely useful tool for the manipulation of terms with bound variables.

We study two kinds of rewrite systems: *Pattern Rewrite Systems* (PRSs) and the more general *Higher-Order Rewrite Systems* (HRSs). PRSs are similar to Klop's *Combinatory Reduction Systems* (CRSs) [16, 18]. Both are generalizations of *Term-Rewriting Systems* (TRSs) [5] to terms with higher-order functions and bound variables. The main difference is that PRSs use the typed λ-calculus as a meta-language, whereas CRSs come with their own untyped abstraction and substitution mechanism. The precise relationship between the two formalisms is explored elsewhere [30]: it is shown that a CRS can be simulated directly by a PRS, whereas the reverse simulation is quite involved. As a consequence, results like confluence carry over very easily

from PRSs to CRSs, but not so easily in the other direction. Although there are these technical differences, the abstraction mechanism in both PRSs and CRSs is general enough to represent quantification in formulae, abstraction in functional programs, and many other variable-binding constructs. Using this representation, many operations on formulae and programs can be expressed naturally as higher-order rewrite systems.

In Section 2 we review the terminology and notation of the typed λ-calculus which is used to define object-level rewrite systems, and define some basic properties. In Section 3 we define Higher-Order Rewrite Systems (HRSs), Pattern Rewrite Systems (PRSs), the reduction relation they induce on terms and show how they interact with substitutions. Then we show how HRSs induce an equality on terms and how it relates to reduction. In Section 4 the Critical Pair Lemma from Knuth and Bendix is generalized to PRSs. In Section 5 a theorem due to Huet about confluence modulo equality is generalized to PRSs. In Section 6 we deal with Orthogonal Pattern Rewrite Systems (OPRSs). These are a special kind of PRSs that have no critical pairs and whose rewrite rules are all left linear. In this section we give two different proofs that OPRSs are confluent. The paper closes with a discussion of related work.

2 Preliminaries

What follows is a description of the meta-language of simply typed λ-calculus which is used to define object-level rewrite systems. The notation is roughly consistent with the standard literature [4, 10].

Starting with some fixed set of **base types** $\mathcal{B}$ the set of all **types** $\mathcal{T}$ is the closure of $\mathcal{B}$ under the function space constructor $\rightarrow$. The letter τ is used to denote types. Function types associate to the right: $\tau_1 \rightarrow \tau_2 \rightarrow \tau_3$ means $\tau_1 \rightarrow (\tau_2 \rightarrow \tau_3)$. Instead of $\tau_1 \rightarrow \ldots \rightarrow \tau_n \rightarrow \tau$ we also write $\overline{\tau_n} \rightarrow \tau$, if τ is a base type.

Terms are generated from a set of typed **variables** $V = \bigcup_{\tau \in \mathcal{T}} V_\tau$ and a set of typed **constants** $C = \bigcup_{\tau \in \mathcal{T}} C_\tau$, where $V_\tau \cap V_{\tau'} = C_\tau \cap C_{\tau'} = \{\}$ if $\tau \neq \tau'$, by λ-abstraction and application. Arbitrary variables are denoted by x, y and z, free variables by upper case letters F, G and H, and constants by c, d, f and g. **Atoms** are constants or variables and are denoted by a and b. Terms are denoted by l, r, s, t and u. We write $t : \tau$ to indicate that a term t is of type τ. The inductive definition of **simply typed** λ-terms is as follows:

$$\frac{x \in V_\tau}{x : \tau} \quad \frac{c \in C_\tau}{c : \tau} \quad \frac{s : \tau \rightarrow \tau' \quad t : \tau}{(s\ t) : \tau'} \quad \frac{x : \tau \quad s : \tau'}{(\lambda x.s) : \tau \rightarrow \tau'}$$

In the sequel all our λ-terms are assumed to be simply typed.

Instead of $\lambda x_1 \ldots \lambda x_n.s$ we also write $\lambda x_1, \ldots, x_n.s$ or just $\lambda \overline{x_n}.s$, where the x_i are assumed to be distinct. Similarly instead of $(\ldots(t\ u_1)\ldots)u_n$ we write $t(u_1, \ldots, u_n)$ or just $t(\overline{u_n})$. The notation $t(\overline{u_n})$ includes the possibility $n = 0$ if t is of base type. The **free** and **bound** variables occurring in a term s are denoted by $fv(s)$ and $bv(s)$, respectively. A term is called **linear** iff no free variable occurs in it more than once.

We assume the usual definition of α, β and η conversion between λ-terms. We write $s =_\gamma t$, where $\gamma \in \{\alpha, \beta, \eta\}$ if s and t are equivalent modulo γ-conversion. In the sequel α-equivalent terms are identified.

As the simply typed λ-calculus is confluent and terminating w.r.t. β-reduction (η-reduction) every term t has a β-normal form (η-normal form) which is denoted $t{\downarrow_\beta}$ ($t{\downarrow_\eta}$). Let t be in β-normal form. Then t is of the form $\lambda \overline{x_k}.a(\overline{u_m})$, where a is called the **head** of t. The **η-expanded** form of t is defined by

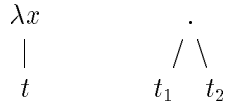
$$t{\uparrow^\eta} = \lambda \overline{x_{n+k}}.a(\overline{u_m}{\uparrow^\eta}, x_{n+1}{\uparrow^\eta}, \ldots, x_{n+k}{\uparrow^\eta})$$

where $t : \overline{\tau_{n+k}} \rightarrow \tau$ and $x_{n+1}, \ldots, x_{n+k} \notin fv(\overline{u_m})$. Instead of $t{\downarrow_\beta}{\uparrow^\eta}$ we write $t{\updownarrow^\eta_\beta}$. A λ-term t is in **long $\beta\eta$-normal form** iff $t = t{\updownarrow^\eta_\beta}$.

Convention: Unless stated otherwise, the variables r, s, t, etc., range over λ-terms in long $\beta\eta$-normal form.

Terms can also be viewed as trees. Subterms can be numbered by so-called **positions** which are the paths from the root to the subterm in Dewey decimal notation. Details can be found in [11, 5]. We just briefly review the notation. The **positions** in a term t are denoted by $\mathcal{P}os(t) \subseteq \mathbb{N}^*$. The letters p and q stand for positions. The root position is ε, the empty sequence. Two positions p and q are appended by juxtaposing them: pq. The letter i is reserved for natural numbers and $i.p$ is the position obtained by appending i to the front of p. Given $p \in \mathcal{P}os(t)$, t/p is the subterm of t at position p; $t[u]_p$ is t with t/p replaced by u.

Abstractions and applications yield the following trees:



Formally this is defined as follows:

$$\begin{array}{rcl} t/\epsilon & = & t \\ (t_1\ t_2)/(i.p) & = & t_i/p \\ (\lambda x.t)/(1.p) & = & t/p \end{array}$$

Hence positions in λ-terms are sequences over $\{1, 2\}$. Note that the bound variable in an abstraction is not a separate subterm and can therefore not be accessed by the s/p notation. For $p_1, p_2 \in Pos(t)$ we define the partial ordering $p_1 \leq p_2$ iff p_1 is a prefix of p_2. We write $p_1 \parallel p_2$ iff neither $p_1 \leq p_2$ nor $p_2 \leq p_1$. If $p_1 \leq p_2$, the position $p_2/p_1 \in Pos(t/p_1)$ is defined as p_2 without the prefix p_1.

Substitutions are finite mappings from variables to terms of the same type. Substitutions are denoted by θ, σ and δ. For $\theta = \{x_1 \mapsto t_1, \ldots, x_n \mapsto t_n\}$ we define $Dom(\theta) = \{x_1, \ldots, x_n\}$ and $Cod(\theta) = \{t_1, \ldots, t_n\}$. The application of a substitution to a term is defined by $\theta(t) := (\lambda\overline{x_k}.t)(\overline{t_n})\downarrow^{\eta}_{\beta}$. We often drop the parentheses and simply write θt.

Let θ_1 and θ_2 be substitutions. Then $\theta_1 + \theta_2$ is a substitution with

$$Dom(\theta_1 + \theta_2) := Dom(\theta_1) \ \cup \ \mathcal{D}om(\theta_2)$$

defined by

$$(\theta_1 + \theta_2)(F) := \begin{cases} \theta_2(F) & \text{if } F \in Dom(\theta_2) \\ \theta_1(F) & \text{otherwise} \end{cases}$$

A **renaming** ρ is an injective substitution with $Cod(\rho) \subset V$ and $Dom(\rho) \cap Cod(\rho) = \{\}$. Renamings are always denoted by ρ.

Note that we will always assume that the domain of a substitution does not contain any variable bound in a term the substitution is applied to. If necessary, the bound variables are renamed automatically.

Two terms s and t are called **unifiable** iff there is a substitution θ, such that $\theta(s) = \theta(t)$. The term s **matches** the term t iff there is a substitution θ, such that $\theta(s) = t$. The problem to decide if a term s matches a term t and to compute the substitution θ is called the **matching problem**, which is very important for rewriting (see the remarks after Definition 3.3).

Given $p \in \mathcal{P}os(t)$, $bv(t, p)$ is the list of all λ-abstracted variables on the path from the root of t to p:

$$\begin{array}{rcl} bv(t, \varepsilon) & = & [] \\ bv((t_1\ t_2), i.p) & = & bv(t_i, p) \\ bv(\lambda x.t, 1.p) & = & x.bv(t, p) \end{array}$$

It is frequently necessary to "lift" a term into a context of certain bound variables. An $\overline{x_k}$-**lifter** of a term t **away from** W is a substitution $\sigma = \{F \mapsto (\rho F)(\overline{x_k}) \mid F \in fv(t)\}$ where ρ is a renaming such that $\mathcal{D}om(\rho) = fv(t), \mathcal{C}od(\rho) \cap W = \{\}$ and $\rho F : \tau_1 \to \cdots \to \tau_k \to \tau$ if $x_1 : \tau_1$, $\ldots$, $x_k : \tau_k$ and $F : \tau$.

For example $\sigma = \{F \mapsto G(x), S \mapsto T(x)\}$ is an x-lifter of $f(\lambda y.g(F(y)), S)$ away from any W not containing G or T; the corresponding renaming is $\rho = \{F \mapsto G, S \mapsto T\}$.

Definition 2.1 We define the **order** of a type in the traditional way:

$$\begin{aligned} ord(\tau) &= 1 \qquad \text{if } \tau \text{ is a base type} \\ ord(\tau_0 \to \tau_1) &= max\{ord(\tau_0) + 1, ord(\tau_1)\} \end{aligned}$$

The **order** of a substitution is the maximal order of the types of the variables in its domain:

$$ord(\theta) = max\{ord(\tau) \mid V_\tau \cap \mathcal{D}om(\theta) \neq \{\}\}$$

Note that $ord(\{\})$, i.e. $max\{\}$ is defined to be 0.

Given a relation $\to$, $\xrightarrow{=}$ denotes the reflexive closure, $\leftrightarrow$ the symmetric closure and $\xrightarrow{*}$ the transitive and reflexive closure of $\to$. We write $s \downarrow t$ iff there is a u, such that $s \xrightarrow{*} u$ and $t \xrightarrow{*} u$. The relation $\to$ is **(locally) confluent** if $r \xrightarrow{*} s$ ($r \to s$) and $r \xrightarrow{*} t$ ($r \to t$) imply $s \downarrow t$. The relation $\to$ is **terminating** if there is no infinite sequence $s_i \to s_{i+1}$ for all $i \in \mathbb{N}$. It is well known that terminating relations are confluent iff they are locally confluent [11].

3 Higher-Order Rewrite Systems

Higher-Order Rewrite Systems are generalizations of first-order rewrite systems [5] to terms with higher-order functions and bound variables. Since unifiability of λ-terms is undecidable in general [8], we often restrict to a certain subclass of λ-terms which behave very much like first-order terms w.r.t. unification.

Definition 3.1 A λ-term t in β-normal form is called a (higher-order) **pattern** if every free occurrence of a variable F is in a subterm $F(\overline{u_n})$ of t, such that $\overline{u_n}$ is η-equivalent to a list of *distinct* bound variables.

Examples of higher-order patterns are $\lambda x.c(x)$, F, $\lambda x.F(\lambda z.x(z))$ and $\lambda x, y.F(y, x)$. Examples of non-patterns are $F(c)$, $\lambda x.F(x, x)$, $\lambda x, y.F(y, c)$ and $\lambda x.G(H(x))$.

The following crucial result about unification of patterns is due to Dale Miller [23]:

Theorem 3.2 *It is decidable whether two patterns are unifiable; if they are unifiable, a most general unifier can be computed.*

Nipkow [26] presents a simplified form of Miller's unification algorithm and develops it towards a practical implementation. Qian [36] shows that patterns can be unified in linear time.

Definition 3.3 A **rewrite rule** is a pair $l \to r$ such that l is not a free variable, l and r are of the same *base* type, and $fv(l) \supseteq fv(r)$. A **pattern rewrite rule** is a rewrite rule whose left-hand side is a pattern. A **Higher-Order Rewrite System** (**HRS**) is a set of rewrite rules. A **Pattern Rewrite System** (**PRS**) is a set of pattern rewrite rules. The letter R always denotes an HRS (which will often be a PRS). A HRS R induces a relation $\to_R$ on terms:

$$s \underset{R}{\to} t \quad \Leftrightarrow \quad \exists (l \to r) \in R, p \in \mathcal{P}os(s), \theta.\ s/p = \theta l \ \wedge \ t = s[\theta r]_p.$$

A rewrite rule is called **left-linear** iff its left-hand side is linear. A HRS is called **left-linear** iff all its rewrite rules are left-linear.

Our HRSs are exactly Wolfram's "higher-order term rewriting systems" [41].

A few remarks are in order:

- Recall that by convention l, r, s and t are in long $\beta\eta$-normal form.
- Due to the restrictions placed on left-hand sides, they must always be of the form $c(\overline{s_n})$.
- For PRSs, the restriction $fv(l) \supseteq fv(r)$ is preserved under substitution. Thus it has the same effect as for TRSs: rewriting cannot introduce new variables. This fails for general HRSs: although $f(F(X)) \to g(X)$ meets the restriction, replacing F by $\lambda x.Y$ yields $f(Y) \to g(X)$ which violates the restriction. This problem is investigated in more detail by Kahrs [15].

  Since we derive only very basic results about HRSs, we do not need to impose anything like $fv(l) \supseteq fv(r)$, whereas the latter is essential for the confluence results for PRSs.
- The restriction to rules of base type is necessary because of the simple matching procedure inherent in the definition of $\to_R$. Otherwise $\overset{*}{\leftrightarrow}_R$ and $=_R$ do not coincide (see section 3.1). Pulling rules down to base type by applying them to new variables is fine for HRSs but may fail for PRSs: $\lambda x.c(F(x))$ is a pattern but ceases to be one when pulled down to base type: $c(F(X))$.
- $\to_R$ is defined only between terms in long $\beta\eta$-normal form. This simplifies technicalities. Alternatively we could work with a relation $\rightsquigarrow_R$ defined by $s \rightsquigarrow_R t :\Leftrightarrow s\downarrow^{\eta}_{\beta} \to_R t\downarrow^{\eta}_{\beta}$.
- The relation $\to_R$ is decidable if the matching problem is decidable for the left-hand sides of the rules in R. As by Theorem 3.2 even unifiability is decidable for patterns, the relation $\to_R$ is decidable for any PRS R; full unification will come in handy in connection with critical pairs.

  For general HRSs the situation is different. Although unifiability is known to be undecidable even for second order λ-terms [8], it is not known whether higher-order matching is decidable. Padovani [32] proved that 4th order matching is decidable, but the general case is still open.

Example 3.4 The standard example of a PRS is pure lambda-calculus itself. The syntax involves just the type $term$ of terms and two constants for abstraction and application:

$$\begin{array}{ll} abs: & (term \to term) \to term \\ app: & term \to term \to term \end{array}$$

The rewrite rules are:

$$\begin{array}{rrcl} beta: & app(abs(\lambda x.F(x)), S) & \to & F(S) \\ eta: & abs(\lambda x.app(S, x)) & \to & S \end{array}$$

Note how the use of meta-level application and abstraction removes the need for a substitution operator (in the $beta$-rule) and side conditions (in the eta-rule).

The following lemma is a simple consequence of the fact that all rewrite rules must be of base type:

Lemma 3.5 *If R is an HRS and $\lambda x.s \to_R t$ then $t = \lambda x.u$ and $s \to_R u$ for some u.*

In the sequel it will be convenient to have an inference-rule based formulation of rewriting.

Definition 3.6 Given an HRS R, let $\Rightarrow_R$ be the least relation on terms in long $\beta\eta$-normal form which is closed under the following rules:

$$\frac{(l \to r) \in R}{\theta l \Rightarrow_R \theta r} \qquad \frac{s \Rightarrow_R t}{a(\overline{s_m}, s, \overline{u_n}) \Rightarrow_R a(\overline{s_m}, t, \overline{u_n})} \qquad \frac{s \Rightarrow_R t}{\lambda x.s \Rightarrow_R \lambda x.t}$$

where a is an atom of type $\overline{\tau_{m+1+n}} \to \tau$.

Of course the two definitions of rewriting are equivalent.

Lemma 3.7 *If R is an HRS then $\to_R$ and $\Rightarrow_R$ coincide.*

Proof The containment $\Rightarrow_R \subseteq \to_R$ is shown by induction on the structure of $\Rightarrow_R$, the reverse containment by induction on the length of p in the definition of $\to_R$. □

In the sequel we will not distinguish $\to_R$ and $\Rightarrow_R$ and use whichever definition is most appropriate. In addition we usually drop the subscript $_R$ and simply write $\to$.

We will now prove an important theorem about $\xrightarrow{*}$, namely its stability under substitution. For TRSs this is simple and one obtains the stronger result that $s \to t$ implies $\theta s \to \theta t$. For HRSs we have to replace $\to$ by $\xrightarrow{*}$ because β-reductions during the application of a substitution can copy redexes. These copies need to be reduced sequentially; hence the use of $\xrightarrow{*}$ instead of $\to$. Later on we will see that a suitable notion of parallel reduction leads to a much nicer stability result (Lemma 6.4).

Definition 3.8 Let $\to$ be an arbitrary relation on terms. We define $\theta \to \theta'$ to mean that $\theta(F) \to \theta'(F)$ holds for all $F \in \mathcal{D}om(\theta)$.

Theorem 3.9 *Let R be an HRS. If $s \xrightarrow{*} s'$ and $\theta \xrightarrow{*} \theta'$ then $\theta s \xrightarrow{*} \theta' s'$.*

Proof by induction on the order of θ (see Definition 2.1) with a nested induction on the length of the derivation $s \xrightarrow{*} s'$.

1. If $s = s'$, we prove $\theta s \xrightarrow{*} \theta' s$ by induction on the structure of s. The structure of normal forms dictates that $s = \lambda\overline{x_m}.a(\overline{s_n})$. The innermost induction hypothesis implies $\theta s_i \xrightarrow{*} \theta' s_i$. Now we distinguish two cases.

   (a) If $a \notin \mathcal{D}om(\theta)$ (and hence $a \notin \mathcal{D}om(\theta')$ because the left-hand side of a rewrite rule cannot match a variable) then $\theta s = \lambda\overline{x_m}.a(\overline{\theta s_n}) \xrightarrow{*} \lambda\overline{x_m}.a(\overline{\theta' s_n}) = \theta' s$ follows easily.

   (b) If $a \in \mathcal{D}om(\theta)$ then $\theta a = \lambda\overline{y_n}.t$. By Lemma 3.5 it follows that $\theta' a = \lambda\overline{y_n}.t'$ where $t \xrightarrow{*} t'$. Define the substitutions $\delta = \{\overline{y_n \mapsto \theta s_n}\}$ and $\delta' = \{\overline{y_n \mapsto \theta' s_n}\}$ and notice that we have $\delta \xrightarrow{*} \delta'$. If a is of type $\overline{\tau_n} \to \tau$, the definition of ord implies $ord(\tau_i) < ord(\overline{\tau_n} \to \tau)$ and hence $ord(\delta) < ord(\theta)$ (note that this also holds in case $n = 0$). Thus the outermost induction hypothesis applies: $\delta t \xrightarrow{*} \delta' t'$ because $t \xrightarrow{*} t'$. Thus we obtain: $\theta s = \lambda\overline{x_m}.(\theta a)(\overline{\theta s_n})\downarrow_\beta = \lambda\overline{x_m}.(\delta t) \xrightarrow{*} \lambda\overline{x_m}.(\delta' t') = \lambda\overline{x_m}.(\theta' a)(\overline{\theta' s_n})\downarrow_\beta = \theta' s$.

2. If $s \xrightarrow{*} s' \to s''$, the inner induction hypothesis yields $\theta s \xrightarrow{*} \theta' s'$. We show $\theta' s' \xrightarrow{*} \theta' s''$ by induction on the structure of the derivation $s' \to s''$ as in Definition 3.6.

   (a) If $s' = \delta l$ and $s'' = \delta r$ for some $(l \to r) \in R$, $\theta' s' = \theta' \delta l = (\theta' \delta) l \to (\theta' \delta) r = \theta' \delta r = \theta' s''$.

   (b) If $s' = \lambda x.t'$ and $s'' = \lambda x.t''$ such that $t' \to t''$, the innermost induction hypothesis yields $\theta' t' \to \theta' t''$ and hence $\theta' s' = \lambda x.\theta' t' \xrightarrow{*} \lambda x.\theta' t'' = \theta' s''$.

   (c) If $s' = a(\overline{s'_n})$, $s'' = a(\overline{s''_n})$ such that $s'_k \to s''_k$ for some k and $s'_i = s''_i$ for all $i \neq k$, then the innermost induction hypothesis yields $\theta' s'_k \xrightarrow{*} \theta' s''_k$. Because $\theta' s'_i \xrightarrow{*} \theta' s''_i$ holds trivially for all $i \neq k$, we obtain $\theta' s'_i \xrightarrow{*} \theta' s''_i$ for all i. Now we distinguish two cases.

i. If $a \notin \mathcal{D}om(\theta')$ then $\theta' s' = a(\overline{\theta' s'_n}) \xrightarrow{*} a(\overline{\theta' s''_n}) = \theta' s''$ follows easily.

ii. If $a \in \mathcal{D}om(\theta')$ then $\theta' a = \lambda \overline{y_n}.t$. Define the new substitutions $\delta' = \{\overline{y_n \mapsto \theta' s'_n}\}$ and $\delta'' = \{\overline{y_n \mapsto \theta' s''_n}\}$ and notice that we have $\delta \xrightarrow{*} \delta'$. As above, we can show that $ord(\delta') < ord(\theta')$; because $\rightarrow$ preserves types, we also have $ord(\theta') = ord(\theta)$. Thus the outermost induction hypothesis applies: $\delta' t \xrightarrow{*} \delta'' t'$ because $t \xrightarrow{*} t$. Thus we obtain: $\theta' s' = (\theta' a)(\overline{\theta' s'_n})\downarrow_\beta = \delta' t \xrightarrow{*} \delta'' t = (\theta' a)(\overline{\theta' s''_n})\downarrow_\beta = \theta' s''$. □

This theorem has two obvious corollaries:

- $s \xrightarrow{*} s'$ implies $\theta s \xrightarrow{*} \theta s'$ and
- $\theta \xrightarrow{*} \theta'$ implies $\theta s \xrightarrow{*} \theta' s$.

However, the above proof fails if one reduces the statement of the theorem to one of the corollaries.

A slightly different version of Theorem 3.9 is also shown by Loría [20]: he uses conditional rewrite rules whose left-hand sides are patterns; his proof relies more on considerations about term positions.

Finally we lift Theorem 3.9 from $\xrightarrow{*}$ to $\overset{*}{\leftrightarrow}$, at least for a special case:

Corollary 3.10 *Let R be an HRS. If $s \overset{*}{\leftrightarrow} s'$ and $t \overset{*}{\leftrightarrow} t'$ then $\{x \mapsto t\}s \overset{*}{\leftrightarrow} \{x \mapsto t'\}s'$.*

Proof If $s_1 \leftrightarrow s_2 \cdots \leftrightarrow s_m$ and $t_1 \leftrightarrow t_2 \cdots \leftrightarrow t_n$, let $\theta_i = \{x \mapsto t_i\}$. Now Theorem 3.9 implies $\theta_1 s_1 \overset{*}{\leftrightarrow} \theta_2 s_1 \overset{*}{\leftrightarrow} \cdots \overset{*}{\leftrightarrow} \theta_n s_1 \overset{*}{\leftrightarrow} \theta_n s_2 \overset{*}{\leftrightarrow} \cdots \overset{*}{\leftrightarrow} \theta_n s_m$. □

The general case, i.e. if $\theta \overset{*}{\leftrightarrow} \theta'$ and $s \overset{*}{\leftrightarrow} s'$ then $\theta s \overset{*}{\leftrightarrow} \theta' s'$, is rather more tedious to derive and is left as an exercise.

3.1 Rewriting versus Equality

Originally, term rewriting was a means of analyzing equational theories, but it has long since taken on a life of its own. Returning to those roots we need to relate our notion of rewriting to a more "logical" notion of equality. In the sequel E will always denote a set of **equations**, i.e. a set of pairs $s = t$, where s and t are terms of the same type. In particular any rewrite rule $l \rightarrow r$ can also be viewed as an equation $l = r$.

Throughout this subsection we do not assume that terms or substitutions are in any normal form and θt denotes the non-normalizing application of θ to t.

Definition 3.11 A set of equations E induces a relation $=_E$ defined by the following inference rules, which come in three groups:

- Basic conversion rules:

$$\frac{(s = t) \in E}{\theta s =_E \theta t}\ (E) \qquad \frac{s =_\beta t}{s =_E t}\ (\beta) \qquad \frac{s =_\eta t}{s =_E t}\ (\eta)$$

- Equality rules:

$$\frac{}{s =_E s}\ (refl) \qquad \frac{s =_E t}{t =_E s}\ (sym) \qquad \frac{r =_E s \quad s =_E t}{r =_E t}\ (trans)$$

- Congruence rules:

$$\frac{s_1 =_E t_1 \quad s_2 =_E t_2}{(s_1\ s_2) =_E (t_1\ t_2)}\ (app) \qquad \frac{s =_E t}{\lambda x.s =_E \lambda x.t}\ (abs)$$

We call $=_E$ the **equational theory** generated by E.

Note that θ in (E) is present only for convenience: substitution can be simulated by (abs), (app) and (β).

Modulo $\updownarrow_\beta^\eta$ we have the same relationship between $\to_R$ and $=_R$ as in the first order case. This can be viewed as a justification of our definition of $\to_R$.

Theorem 3.12 *If R is an HRS then $s =_R t \;\Leftrightarrow\; s\updownarrow_\beta^\eta \overset{*}{\leftrightarrow}_R t\updownarrow_\beta^\eta$.*

Proof The $\Leftarrow$-direction is easy since $=_R$ can mimic $\overset{*}{\leftrightarrow}$ directly. If $s\updownarrow_\beta^\eta \overset{*}{\leftrightarrow} t\updownarrow_\beta^\eta$ then $s \overset{*}{\to}_\beta s_\beta \overset{*}{\leftarrow}_\eta s_\eta \overset{*}{\leftrightarrow} t_\eta \overset{*}{\to}_\eta t_\beta \overset{*}{\leftarrow}_\beta t$. The reductions $\to_\beta$ and $\to_\eta$ are subsumed by (β) and (η); every $\leftrightarrow$ is replaced by a single (E), possibly combined with (sym), embedded in a tree of congruence and reflexivity rules. Everything is held together with a finite amount of $(trans)$.

For the $\Rightarrow$-direction assume $s =_R t$. By induction on the structure of the derivation of $s =_R t$, considering each rule in turn, we prove $s\updownarrow_\beta^\eta \overset{*}{\leftrightarrow} t\updownarrow_\beta^\eta$.

(E): $s = \theta l$ and $t = \theta r$ for some $(l \to r) \in R$. Thus $l \to r$ and hence $s\updownarrow_\beta^\eta = (\theta l)\updownarrow_\beta^\eta \overset{*}{\to} (\theta r)\updownarrow_\beta^\eta = t\updownarrow_\beta^\eta$ by Theorem 3.9.

$(\beta), (\eta), (refl)$: trivial because $s\updownarrow_\beta^\eta = t\updownarrow_\beta^\eta$.

$(trans), (sym)$: by induction hypothesis because $\overset{*}{\leftrightarrow}$ is transitive and symmetric.

(abs): by induction hypothesis because $s'\updownarrow_\beta^\eta \overset{*}{\leftrightarrow} t'\updownarrow_\beta^\eta$ implies $(\lambda x.s')\updownarrow_\beta^\eta \overset{*}{\leftrightarrow} (\lambda x.t')\updownarrow_\beta^\eta$.

(app): $s = (s_1\ s_2)$ and $t = (t_1\ t_2)$. By induction hypothesis we have $s_i\updownarrow_\beta^\eta \overset{*}{\leftrightarrow} t_i\updownarrow_\beta^\eta$. Since s_1 and t_1 are of functional type, $s_1\updownarrow_\beta^\eta$ must be of the form $\lambda x.s_1'$ and $t_1\updownarrow_\beta^\eta$ of the form $\lambda x.t_1'$. Thus Lemma 3.5 implies $s_1' \overset{*}{\leftrightarrow} t_1'$. Let $\theta = \{x \mapsto s_2\updownarrow_\beta^\eta\}$ and $\theta' = \{x \mapsto t_2\updownarrow_\beta^\eta\}$. Corollary 3.10 yields $s\updownarrow_\beta^\eta = ((\lambda x.s_1')s_2)\updownarrow_\beta^\eta = (\theta s_1')\updownarrow_\beta^\eta \overset{*}{\leftrightarrow} (\theta' t_1')\updownarrow_\beta^\eta = ((\lambda x.t_1')t_2)\updownarrow_\beta^\eta = t\updownarrow_\beta^\eta$. □

Thus we know that undirected rewriting and equational logic coincide. Note that the proof sketch in [25] is considerably more involved because Theorem 3.9 is not available.

Now we can use the fact that for confluent reductions convertibility and existence of a common reduct coincide:

Corollary 3.13 *If R is a confluent HRS then $s =_R t \;\Leftrightarrow\; s\updownarrow_\beta^\eta \downarrow_R t\updownarrow_\beta^\eta$.*

Loría [20, Thm. 5.1.2] follows [25] to prove the same result for conditional PRSs. Wolfram [41, Thm. 4.11] appears to prove the same result, but all of his equations are by definition in long $\beta\eta$-normal form and a proof of the (app)-case of his theorem would require something like Theorem 3.9 above or Theorem 3.11 of [25].

It should be pointed out that Theorem 3.12 fails for rules of function type. The one-rule system

$$R = \{\lambda x.c(x, F(x)) \to \lambda x.d(F(x), x)\}$$

induces a relation $\overset{*}{\leftrightarrow}$ which is strictly weaker than $=_R$: $c(a, f(a)) =_R d(f(a), a)$ holds but $c(a, f(a)) \overset{*}{\leftrightarrow} d(f(a), a)$ does not hold because the definition of $\to$ insists on rewriting β-normal forms only. Otherwise one could β-expand $c(f(a), a)$ to $(\lambda x.c(x, f(x)))a$ before rewriting it to $(\lambda x.d(f(x), x))a$.

4 The Critical Pair Lemma

In 1972, Knuth and Bendix [19] showed that confluence of terminating rewrite systems is decidable: a simple test of confluence for the finite set of so called critical pairs suffices. Later this result was generalized to PRSs by Nipkow [25], although no proof was given at the time. The purpose of this section is to supply the missing proof and at the same time prepare the ground for the related issue of confluence modulo equality which is treated in the following section.

Definition 4.1 Let there be two rewrite rules $l_i \to r_i$, $i = 1,2$, in a PRS and a position $p \in Pos(l_1)$ such that

- $fv(l_1) \cap bv(l_1) = \{\}$,
- the head of l_1/p is not a free variable in l_1, and
- the two patterns $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.(\sigma l_2)$, where $\{\overline{x_k}\} = bv(l_1,p)$ and σ is an $\overline{x_k}$-lifter of l_2 away from $fv(l_1)$, have a most general unifier θ.

Then the pattern l_1 **overlaps** the pattern l_2 at position p. The rewrite rules determine the **critical pair** $\langle \theta r_1, \theta(l_1[\sigma r_2]_p)\rangle$. Note that because $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.(\sigma l_2)$ unify, l_1/p must be of the form $f(\ldots)$.

Two redexes t/p_1 and t/p_2 in a term t are **overlapping** if there are rewrite rules $l_i \to r_i$, $i = 1,2$, such that $p_1 \le p_2$, $t/p_1 = \theta_1 l_1$, $t/p_2 = \theta_2 l_2$ and l_1 overlaps l_2 at position p_2/p_1.

The **critical pairs** of a PRS R are all the critical pairs arising from overlapping two left-hand sides of rules in R, except for a left-hand side of a rule overlapping itself at position ϵ. Note that it is possible that a left-hand side l of a rule $l \to r$ overlaps itself at positions $p \neq \epsilon$ thus giving rise to a critical pair.

As this definition is difficult to handle, the following lemmas will be useful for dealing with critical pairs. Let us first show that critical pairs represent rewrite peaks:

Lemma 4.2 *Let $\langle u_1, u_2\rangle$ be a critical pair. Then there exists a term s such that $u_1 \leftarrow s \to u_2$.*

Proof Let $u_1 = \theta r_1$ and $u_2 = \theta(l_1[\sigma r_2]_p)$ as in Definition 4.1 and define $s := \theta l_1$. Thus $s \to \theta r_1 = u_1$ is trivial. We also have $\lambda\overline{x_k}.\theta(l_1/p) = \theta(\lambda\overline{x_k}.(l_1/p)) = \theta(\lambda\overline{x_k}.(\sigma l_2)) = \lambda\overline{x_k}.(\theta\sigma l_2)$, because $fv(l_1) \cap bv(l_1) = \{\}$. Therefore $\theta(l_1/p) = \theta\sigma l_2$. As l_1 is a pattern and l_1/p is of the form $f(\ldots)$, we also have $p \in \mathcal{P}os(\theta l_1)$ and $(\theta l_1)/p = \theta\sigma l_2$. So we get $s = (\theta l_1)[\theta\sigma l_2]_p \to (\theta l_1)[\theta\sigma r_2]_p = \theta(l_1[\sigma r_2]_p) = u_2$. □

Lemma 4.3 *Let there be two patterns l_1, l_2, a position $p \in Pos(l_1)$ where l_1/p is not of the form $F(\ldots)$, $\{\overline{x_k}\} = bv(l_1,p)$ and an $\overline{x_k}$-lifter σ of l_2 away from $fv(l_1)$. Then the two patterns $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.\sigma(l_2)$ are unifiable iff there exist substitutions θ_1 and θ_2, such that $\theta_1(l_1/p) = \theta_2 l_2$ and $bv(l_1,p) \cap Cod(\theta_1) = \{\}$.*

Proof

1. For the $\Leftarrow$-direction assume w.l.o.g. $Dom(\theta_1) \subseteq fv(l_1)$. Let $\theta_2' := \{\rho(F) \mapsto \lambda\overline{x_k}.\theta_2(F) \mid F \in fv(l_2)\}$ and ρ be the renaming corresponding to σ. We now show that $\theta_0 := \theta_1 \cup \theta_2'$ is a unifier of $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.(\sigma l_2)$. From $\theta_2'\sigma(F) = \theta_2'((\rho(F))(\overline{x_k})) = \theta_2(F)$ for all $F \in fv(l_2)$ it follows that $\theta_2'(\sigma l_2) = \theta_2 l_2$. Therefore

$$
\begin{array}{ll}
\theta_0(\lambda\overline{x_k}.(l_1/p)) = \theta_1(\lambda\overline{x_k}.(l_1/p)) & Dom(\theta_2') \cap fv(l_1) = \{\} \\
= \lambda\overline{x_k}.\theta_1(l_1/p) & bv(l_1,p) \cap Cod(\theta_1) = \{\} \\
= \lambda\overline{x_k}.\theta_2(l_2) & \\
= \lambda\overline{x_k}.\theta_2'(\sigma(l_2)) = \theta_2'(\lambda\overline{x_k}.\sigma(l_2)) & Cod(\theta_2') \cap \{\overline{x_k}\} = \{\} \\
= \theta_0(\lambda\overline{x_k}.\sigma(l_2)) & \sigma \text{ away from } fv(l_1) \supseteq Dom(\theta_1)
\end{array}
$$

2. For the $\Rightarrow$-direction assume that θ is a unifier of $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.(\sigma l_2)$. Define $\theta_1 := \theta|_{fv(l_1)}$ and $\theta_2 := \theta\sigma$. Then we have $\lambda\overline{x_k}.\theta_1(l_1/p) = \theta(\lambda\overline{x_k}.(l_1/p)) = \theta(\lambda\overline{x_k}.(\sigma l_2)) = \lambda\overline{x_k}.\theta_2(l_2)$, because $fv(l_1) \cap bv(l_1) = \{\}$. Therefore $\theta_1(l_1/p) = \theta_2(l_2)$. As θ is a unifier of $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.(\sigma(l_2))$ and $\{\overline{x_k}\} = bv(l_1,p) \subseteq bv(\lambda\overline{x_k}.(l_1/p))$ it follows that $bv(l_1,p) \cap Cod(\theta_1) = \{\}$. □

Lemma 4.4 *Let there be two rules $l_i \to r_i$, $i = 1,2$, and a position $p \in Pos(l_1)$ where l_1/p is not of the form $F(\ldots)$, and substitutions θ_1 and θ_2 such that $\theta_1(l_1/p) = \theta_2(l_2)$ and $bv(l_1,p) \cap Cod(\theta_1) = \{\}$. Then l_1 overlaps l_2 and there exist a critical pair $\langle s,t\rangle$ and a substitution δ with $\delta s = \theta_1 r_1$ and $\delta t = (\theta_1 l_1)[\theta_2 r_2]_p$.*

Proof Because $fv(l_i) \supseteq fv(r_i)$ we can assume $Dom(\theta_1) \subseteq fv(l_1)$. Let $\{\overline{x_k}\} = bv(l_1,p)$ and σ an $\overline{x_k}$-lifter of l_2 away from $fv(l_1)$. It follows from Lemma 4.3 that the two patterns $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.\sigma(l_2)$ are unifiable. Let θ_0 be the unifier as defined in Lemma 4.3. By Lemma 3.2 there is a most general unifier θ of $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.\sigma(l_2)$. Hence l_1 overlaps l_2 at position p and there is a critical pair $\langle s,t\rangle$, such that $s = \theta r_1$ and $t = \theta(l_1[\sigma r_2]_p)$. As θ is a most general unifier there exists a substitution δ with $\theta_0 = \delta\theta$. Hence $\delta s = \theta_0 r_1 = \theta_1 r_1$ and $\delta t = \theta_0(l_1[\sigma r_2]_p) = (\theta_0 l_1)[\theta_0(\sigma r_2)]_p = (\theta_1 l_1)[\theta_2'(\sigma r_2)]_p = (\theta_1 l_1)[\theta_2 r_2]_p$ □

Corollary 4.5 *l_1 overlaps l_2 iff there exist $p \in \mathcal{P}os(l_1)$, θ_1 and θ_2, such that $\theta_1(l_1/p) = \theta_2 l_2$ and $bv(l_1,p) \cap Cod(\theta_1) = \{\}$.*

Proof The $\Leftarrow$-direction follows directly from Lemma 4.4. For the $\Rightarrow$-direction assume that l_1 overlaps l_2. By Definition 4.1 there is a most general unifier of $\lambda\overline{x_k}.(l_1/p)$ and $\lambda\overline{x_k}.(\sigma l_2)$, where $\{\overline{x_k}\} = bv(l_1,p)$ and σ is an $\overline{x_k}$-lifter of l_2 away from $fv(l_1)$. Therefore the result follows from Lemma 4.3. □

Lemma 4.6 (Critical Pair Lemma) *Let R be a PRS and $\to$ the corresponding reduction relation on terms. If $s \to s_i$, $i = 1,2$, then either $s_1 \downarrow s_2$, or there are a critical pair $\langle u_1,u_2\rangle$, a substitution δ and a position $p \in Pos(s)$, such that $s_i = s[\delta u_i]_p$, $i = 1,2$.*

Proof By definition of $s \to s_i$ there are rules $(l_i \to r_i) \in R$, positions $p_i \in Pos(s)$ and substitutions θ_i, such that $s/p_i = \theta_i l_i$ and $s_i = s[\theta_i r_i]_{p_i}$. Depending on the relative positions of the redexes, there are two cases.

1. $p_1 \parallel p_2$. It follows directly that $s_1 = s[\theta_1 r_1]_{p_1} \to s[\theta_1 r_1]_{p_1}[\theta_2 r_2]_{p_2} \leftarrow s[\theta_2 r_2]_{p_2} = s_2$.

2. W.l.o.g. $p_1 \leq p_2$. Let $q := p_2/p_1$. It follows that

$$s_2/p_1 = (s[\theta_2 r_2]_{p_2})/p_1 = (s/p_1)[\theta_2 r_2]_q = (\theta_1 l_1)[\theta_2 r_2]_q$$

and

$$(\theta_1 l_1)/q = (s/p_1)/q = s/p_2 = \theta_2 l_2$$

There are two cases:

(a) The two redexes do not overlap, i.e. $q = q_1 q_2$, such that $q_1 \in Pos(l_1)$ and $l_1/q_1 = F(\overline{x_k})$, with $F \in fv(l_1)$ (remember that l_1 is a pattern). Hence $\theta_1(F)$ is of the form $\lambda\overline{x_k}.t$ and we define the substitution

$$\theta_1' := \theta_1 + \{F \mapsto \lambda\overline{x_k}.(t[\theta_2 r_2]_{q_2})\}$$

It follows that $t/q_2 = (\theta_1(F(\overline{x_k})))/q_2 = (\theta_1(l_1/q_1))/q_2 = ((\theta_1 l_1)/q_1)/q_2 = (\theta_1 l_1)/q = \theta_2 l_2$ and hence $\theta_1 \stackrel{=}{\to} \theta_1'$ (Definition 3.8). By stability (Theorem 3.9) it follows that $\theta_1 r_1 \stackrel{*}{\to} \theta_1' r_1$.

Let H be a new variable (i.e. unused so far in this context) and

$$\begin{array}{lcll} \theta_0 & := & \theta_1 & \cup \quad \{H \mapsto \theta_1'(F)\} \\ \theta_0' & := & \theta_0 & + \quad \{F \mapsto \theta_1'(F)\} \end{array}$$

and $l_0 := l_1[H(\overline{x_k})]_{q_1}$. From $\theta_1 \stackrel{=}{\to} \theta_1'$ it follows that $\theta_0 \stackrel{=}{\to} \theta_0'$. Theorem 3.9 yields $(\theta_1 l_1)[\theta_2 r_2]_q = (\theta_1 l_1)[\theta_1'(F(\overline{x_k}))]_{q_1} = \theta_0 l_0 \stackrel{*}{\to} \theta_0' l_0 = \theta_0' l_1 = \theta_1' l_1 \to \theta_1' r_1$. The step $\theta_0 l_0 \to^* \theta_0' l_0$ is necessary because F may occur more than once in l_1.
Combining all this we obtain $s_1/p_1 = \theta_1 r_1 \stackrel{*}{\to} \theta_1' r_1 \stackrel{*}{\leftarrow} (\theta_1 l_1)[\theta_2 r_2]_q = s_2/p_1$. Placing it in the context it follows that

$$s_1 = s[\theta_1 r_1]_{p_1} \stackrel{*}{\to} s[\theta_1' r_1]_{p_1} \stackrel{*}{\leftarrow} s[(\theta_1 l_1)[\theta_2 r_2]_q]_{p_1} = s[\theta_2 r_2]_{p_2} = s_2$$

and hence $s_1 \downarrow s_2$.

(b) The two redexes overlap, i.e. $q \in Pos(l_1)$ and l_1/q is not of the form $F(\ldots)$. W.l.o.g. let $bv(l_1) \cap Cod(\theta_1) = \{\}$. Thus it follows from Lemma 4.4 that there exist a critical pair $\langle u_1, u_2 \rangle$ and a substitution δ with $\delta u_1 = \theta_1 r_1$ and $\delta u_2 = (\theta_1 l_1)[\theta_2 r_2]_q$. This implies $s_1 = s[\theta_1 r_1]_{p_1} = s[\delta u_1]_{p_1}$ and $s_2 = s[\theta_2 r_2]_{p_2} = s[\theta_1(l_1)[\theta_2 r_2]_q]_{p_1} = s[\delta u_2]_{p_1}$. □

Theorem 4.7 *The relation $\to$ is locally confluent iff $u_1 \downarrow u_2$ for all critical pairs $\langle u_1, u_2 \rangle$ of the PRS R.*

Proof The $\Rightarrow$-direction is a trivial consequence of Lemma 4.2. For the $\Leftarrow$-direction assume $u_1 \downarrow u_2$ for all critical pairs $\langle u_1, u_2 \rangle$ of R. Let $s \to s_i$, $i = 1, 2$. Then the Critical Pair Lemma 4.6 can be applied. In the first of its two cases the result follows immediately. In the second case there is a critical pair $\langle u_1, u_2 \rangle$, a substitution δ and a position $p \in Pos(s)$, such that $s_i = s[\delta u_i]_p$, $i = 1, 2$. By assumption there is a term w, such that $u_1 \stackrel{*}{\to} w \stackrel{*}{\leftarrow} u_2$. Theorem 3.9 yields $\delta u_1 \stackrel{*}{\to} \delta w \stackrel{*}{\leftarrow} \delta u_2$ and hence $s_1 = s[\delta u_1]_p \stackrel{*}{\to} s[\delta w]_p \stackrel{*}{\leftarrow} s[\delta u_2]_p = s_2$. Thus $s_1 \downarrow s_2$ and $\to$ is locally confluent. □

As for terminating relations confluence and local confluence are equivalent, this yields a decision procedure for the confluence of a terminating PRS.

Corollary 4.8 *Confluence of terminating PRSs is decidable.*

Example 4.9 The syntax of classical predicate logic can be described by the two types *term* and *form* of terms and formulae and by the following constants:

$$\begin{array}{rl} \neg: & \mathit{form} \to \mathit{form} \\ \wedge, \vee: & \mathit{form} \to \mathit{form} \to \mathit{form} \\ \forall, \exists: & (\mathit{term} \to \mathit{form}) \to \mathit{form} \end{array}$$

For readability we write $\forall x.P(x)$ instead of $\forall(\lambda x.P(x))$ and use $\wedge$ as an infix.

The **negation normal form** [7], where $\neg$ is only applied to atomic formulae, can be defined via the following terminating[1] rewrite system:

$$\begin{array}{lrcl} \neg\neg: & \neg\neg P & \to & P \\ \neg\wedge: & \neg(P \wedge Q) & \to & (\neg P) \vee (\neg Q) \\ \neg\vee: & \neg(P \vee Q) & \to & (\neg P) \wedge (\neg Q) \\ \neg\forall: & \neg\forall x.P'(x) & \to & \exists x.\neg P'(x) \\ \neg\exists: & \neg\exists x.P'(x) & \to & \forall x.\neg P'(x) \end{array}$$

[1] Termination of this and of the other terminating systems in this paper can be proved with the techniques by van de Pol [34].

There are 5 critical pairs, all of which arise by unifying the left-hand side of some rule with the subterm $\neg P$ of $\neg\neg P$, and all of which are joinable. For example

$$\begin{array}{ccc} & & \exists x.P'(x) \\ & \nearrow_{\neg\neg} & \\ \neg\neg\exists x.P'(x) & & \\ & \searrow_{\neg\exists} & \\ & & \neg\forall x.\neg P'(x) \end{array}$$

is joinable because $\neg\forall x.\neg P'(x) \to \exists x.\neg\neg P'(x) \to \exists x.P'(x)$. Hence the system is confluent, i.e. the negation normal form is uniquely determined.

Example 4.10 Going back to Example 3.4, the pure lambda-calculus, we find that both *beta* and *eta* have no critical pairs with themselves, and hence that *beta* and *eta* on their own are locally confluent. Since *eta* also terminates, this implies confluence. For the non-terminating *beta* we have to wait for the notion of orthogonality to deduce confluence. Combining *beta* and *eta* yields two critical pairs:

$$\begin{array}{ccc} & & app(S,T) \\ & \nearrow_{\beta} & \\ app(abs(\lambda x.app(S,x)),T) & & \\ & \searrow_{\eta} & \\ & & app(S,T) \end{array}$$

$$\begin{array}{ccc} & & abs(\lambda x.F(x)) \\ & \nearrow_{\beta} & \\ abs(\lambda x.app(abs(\lambda y.F(y)),x)) & & \\ & \searrow_{\eta} & \\ & & abs(\lambda y.F(y)) \end{array}$$

Both critical pairs are trivially joinable. Hence $beta + eta$ is locally confluent. In Section 7 we quote a result which even permits to deduce confluence of $beta + eta$.

An interesting extension of this system can be obtained by adding a constant $\bot : term$ representing the completely undefined term, and the two rules

$$\begin{array}{lrcl} \bot app: & app(\bot,S) & \to & \bot \\ \bot abs: & abs(\lambda x.\bot) & \to & \bot \end{array}$$

This system has two critical pairs: *eta* overlaps $\bot app$ yielding $\langle \bot, abs(\lambda x.\bot)\rangle$, and *beta* overlaps $\bot abs$ yielding $\langle \bot, app(\bot,S)\rangle$. This is a nice example of completion: if either of the two rules had been omitted, it would have followed from the other one as a critical pair. Hence the system is locally confluent. Unfortunately, we have no theorem which implies confluence.

One of the main selling points of critical pairs has been the fact that they come with a so-called "completion algorithm": a non-confluent rewrite system can be transformed into an equivalent (w.r.t. the equational theory) but confluent system by adding critical pairs as new reduction rules. As the last example indicates, this is also possible in our higher-order situation. However, higher-order critical pairs may no longer be pattern rewrite rules in case neither of the two components is a pattern. It is easy to see that this unfortunate state cannot arise if the original PRS we start with contains only rewrite rules where both the left and the right-hand sides are patterns, a rare situation in practice.

5 Confluence modulo Equality

The most important consequence of confluence is the uniqueness of normal forms. However, there are cases of non-confluent systems where the normal forms of any term are not unique, but somehow similar to each other.

Example 5.1 In Example 4.9 we showed how to express predicate logic formulae as λ-terms. The **prenex normal form** can be described by a rewrite system R consisting of the rules

$$\begin{array}{rcl} \mathsf{Q}* & : & (\mathsf{Q}x.P'(x)) * Q \;\to\; \mathsf{Q}x.(P'(x) * Q) \\ *\mathsf{Q} & : & P * (\mathsf{Q}x.Q'(x)) \;\to\; \mathsf{Q}x.(P * Q'(x)) \end{array}$$

for all $\mathsf{Q} \in \{\forall, \exists\}$ and $* \in \{\wedge, \vee\}$, together with the rules $\neg\forall$ and $\neg\exists$ from Example 4.9.

This system terminates but is not confluent. This is because $(\mathsf{Q}x.P'(x)) * (\mathsf{Q}y.Q'(y))$ gives rise to the critical pair $\langle r, s\rangle := \langle \mathsf{Q}x.(P'(x) * (\mathsf{Q}y.Q'(y))), \mathsf{Q}y.((\mathsf{Q}x.P'(x)) * Q'(y))\rangle$ which has two distinct normal forms $\mathsf{Q}x.\mathsf{Q}y.(P'(x) * Q'(y))$ and $\mathsf{Q}y.\mathsf{Q}x.(P'(x) * Q'(y))$.

This example shows that commutativity of quantifiers needs to be taken into account as well. Huet [11] introduced the notion of confluence *modulo equality* of first-order term rewriting systems. In this section some of his results are lifted to PRSs.

Let us first look at abstract relations $\to$ and $\sim$.

Definition 5.2 A relation $\to$ is **confluent modulo an equivalence relation** $\sim$ iff

$$x \sim y \wedge x \stackrel{*}{\to} x' \wedge y \stackrel{*}{\to} y' \;\Rightarrow\; \exists x'', y''.\; x' \stackrel{*}{\to} x'' \wedge y' \stackrel{*}{\to} y'' \wedge x'' \sim y''$$

A relation $\to$ is called **normalizing** if for every x there is a y in $\to$-normal form such that $x \stackrel{*}{\to} y$.

Lemma 5.3 (Huet [11]) *Let $\to$ be normalizing and let $x\!\downarrow$ denote an arbitrary normal form of x. Then $\to$ is confluent modulo an equivalence relation $\sim$ iff*

$$x \equiv y \;\Rightarrow\; x\!\downarrow \sim y\!\downarrow$$

where $\equiv$ is $(\leftrightarrow \cup \sim)^*$.

Thus we can replace the test for equivalence modulo $\to \cup \sim$ by a test of $\sim$-equivalence of $\to$-normal forms. If $\to$-normal forms are computable and $\sim$ is decidable, so is $\equiv$.

In the sequel $\cdot$ denotes composition of relations:

$$\to \cdot \sim \;=\; \{(x, z) \mid \exists y.\; x \to y \wedge y \sim z\}$$

Huet also proves a sufficient abstract condition for confluence modulo:

Lemma 5.4 (Huet [11]) *Let $\vdash\!\dashv$ be a symmetric relation, $\sim = \stackrel{*}{\vdash\!\dashv}$ and $\to$ a relation, such that $\to \cdot \sim$ is terminating. Then $\to$ is confluent modulo $\sim$ iff the conditions $\mathcal{A}$ and $\mathcal{B}$ are satisfied:*

$$\begin{array}{rl} \mathcal{A}: & \forall x, y, z.\; x \to y \;\wedge\; x \to z \;\Rightarrow\; y \stackrel{\sim}{\downarrow} z \\ \mathcal{B}: & \forall x, y, z.\; x \vdash\!\dashv y \;\wedge\; x \to z \;\Rightarrow\; y \stackrel{\sim}{\downarrow} z \end{array}$$

where $y \stackrel{\sim}{\downarrow} z \;:\Leftrightarrow\; \exists u, v.\; y \stackrel{*}{\to} u \;\wedge\; z \stackrel{*}{\to} v \;\wedge\; u \sim v$.

We will now concentrate on the application of confluence modulo to PRSs.

Definition 5.5 Let R be a PRS and $\mathcal{E}$ a symmetric PRS. Then $\langle R, \mathcal{E} \rangle$ is called an **equational PRS**.

The PRS R defines a relation $\rightarrow$ on terms as usual. Because $\mathcal{E}$ is a symmetric PRS, for every rule $(l \rightarrow r) \in \mathcal{E}$ the reverse rule $(r \rightarrow l)$ is in $\mathcal{E}$ as well. As $\mathcal{E}$ is a PRS it follows that both l and r are patterns, neither l nor r are free variables and $fv(l) = fv(r)$. The symmetric reduction relation on terms defined by $\mathcal{E}$ is denoted by $\vdash\!\dashv_{\mathcal{E}}$ or simply $\vdash\!\dashv$. The transitive-reflexive closure $\sim := \stackrel{*}{\vdash\!\dashv}$ is an equivalence relation. It is called the equivalence relation defined by $\mathcal{E}$.

Definition 5.6 An equational PRS $\langle R, \mathcal{E} \rangle$ is called **confluent** iff the relation $\rightarrow$ defined by R is confluent modulo the equivalence relation $\sim$ defined by $\mathcal{E}$.

Lemma 5.3 together with Theorem 3.12 implies that $s =_{R \cup \mathcal{E}} t \;\Leftrightarrow\; s\!\downarrow^{\eta}_{\beta}\!\downarrow_R =_{\mathcal{E}} t\!\downarrow^{\eta}_{\beta}\!\downarrow_R$ if R is terminating and $\langle R, \mathcal{E} \rangle$ is confluent. Confluence of equational PRSs can be proved by also considering critical pairs between R and $\mathcal{E}$.

Definition 5.7 Let $\langle R, \mathcal{E} \rangle$ be an equational PRS. The **critical pairs of** $\mathcal{E}/R$ are defined as all critical pairs arising from overlapping (analogous to Definition 4.1) the left-hand sides of rules $(l_1 \rightarrow r_1)$ and $(l_2 \rightarrow r_2)$, where either $(l_1 \rightarrow r_1) \in \mathcal{E}$ and $(l_2 \rightarrow r_2) \in R$ or $(l_1 \rightarrow r_1) \in R$ and $(l_2 \rightarrow r_2) \in \mathcal{E}$.

Definition 5.8 The **critical pairs of** $\langle R, \mathcal{E} \rangle$ are the union of the critical pairs of R and the critical pairs of $\mathcal{E}/R$.

Finally we can generalize Huet's characterizations of conditions $\mathcal{A}$ and $\mathcal{B}$ to equational PRSs:

Lemma 5.9 *$\langle R, \mathcal{E} \rangle$ satisfies condition $\mathcal{A}$ iff $u_1 \stackrel{\sim}{\downarrow} u_2$ for every critical pair $\langle u_1, u_2 \rangle$ of R.*

Proof

1. Assume condition $\mathcal{A}$ and let $\langle u_1, u_2 \rangle$ be a critical pair of R. By Lemma 4.2 there exists a term s such that $u_1 \leftarrow s \rightarrow u_2$. Hence $u_1 \stackrel{\sim}{\downarrow} u_2$ by condition $\mathcal{A}$.

2. Assume $u_1 \stackrel{\sim}{\downarrow} u_2$ for every critical pair $\langle u_1, u_2 \rangle$ of R and $s \rightarrow s_i,\ i = 1, 2$. By the Critical Pair Lemma 4.6 there are two cases:

   (a) $s_1 \downarrow s_2$. By the reflexivity of $\sim$ if follows that $s_1 \stackrel{\sim}{\downarrow} s_2$.

   (b) There is a critical pair $\langle u_1, u_2 \rangle$, a substitution δ and $p \in Pos(s)$, such that $s_i = s[\delta u_i]_p,\ i = 1, 2$. By assumption there are terms u_1', u_2', such that $u_1 \stackrel{*}{\rightarrow} u_1' \sim u_2' \stackrel{*}{\leftarrow} u_2$. Theorem 3.9 yields $\delta u_i \rightarrow^* \delta u_i',\ i = 1, 2$. As $\sim = \stackrel{*}{\vdash\!\dashv}$ and $\vdash\!\dashv$ is defined by a symmetric PRS, Theorem 3.9 also yields $\delta(u_1') \sim \delta(u_2')$. So we get

   $$s_1 = s[\delta u_1]_p \stackrel{*}{\rightarrow} s[\delta u_1']_p \sim s[\delta u_2']_p \stackrel{*}{\leftarrow} s[\delta u_2]_p = s_2$$

   and hence $s_1 \stackrel{\sim}{\downarrow} s_2$.

□

Lemma 5.10 *Let $\langle R, \mathcal{E} \rangle$ be an equational PRS and R left-linear. Condition $\mathcal{B}$ is satisfied iff for every critical pair $\langle u_1, u_2 \rangle$ of $\mathcal{E}/R$ we have $u_1 \stackrel{\sim}{\downarrow} u_2$.*

Proof

1. Assume condition $\mathcal{B}$. Let $\langle u_1, u_2\rangle$ be a critical pair of $\mathcal{E}/R$. There is a rule $(l_1 \to r_1) \in R$ and a rule $(l_2 \to r_2) \in \mathcal{E}$, such that w.l.o.g. l_1 overlaps l_2. By Lemma 4.2 there is a term s, such that $u_1 \leftarrow s \vdash\!\!\to u_2$. Hence condition $\mathcal{B}$ yields $u_1 \overset{\sim}{\downarrow} u_2$. The other case where l_2 overlaps l_1 is symmetric.

2. Assume $u_1 \overset{\sim}{\downarrow} u_2$ for every critical pair $\langle u_1, u_2\rangle$ of $\mathcal{E}/R$.
Let $s \to s_1$ and $s \vdash\!\!\to s_2$. By definition of $\to$ and $\vdash\!\!\to$ there are rules $(l_1 \to r_1) \in R$, $(l_2 \to r_2) \in \mathcal{E}$, positions $p_1, p_2 \in Pos(s)$ and substitutions θ_1, θ_2, such that $s/p_1 = \theta_1 l_1$, $s_1 = s[\theta_1 r_1]_{p_1}$, $s/p_2 = \theta_2 l_2$, $s_2 = s[\theta_2 r_2]_{p_2}$. There are three cases:

   (a) $p_1 \parallel p_2$. It is trivial that $s_1 = s[\theta_1 r_1]_{p_1} \vdash\!\!\to s[\theta_1 r_1]_{p_1}[\theta_2 r_2]_{p_2} \leftarrow s[\theta_2 r_2]_{p_2} = s_2$. Hence $s_1 \overset{\sim}{\downarrow} s_2$ and condition $\mathcal{B}$ is satisfied.

   (b) $p_2 \leq p_1$ and $q := p_1/p_2$. It follows that $s_1/p_2 = (s[\theta_1 r_1]_{p_1})/p_2 = (s/p_2)[\theta_1 r_1]_q = (\theta_2 l_2)[\theta_1 r_1]_q$ and $(\theta_2 l_2)/q = (s/p_2)/q = s/p_1 = \theta_1 l_1$. There are two cases:

      i. The two redexes do not overlap, i.e. $q = q_1 q_2$, such that $q_1 \in Pos(l_2)$ and $l_2/q_1 = F(\overline{x_k})$, where $F \in fv(l_2)$ (remember: l_2 is a pattern). Hence $\theta_2(F)$ is of the form $\lambda\overline{x_k}.t$ and we define the substitution

$$\theta_2' := \theta_2 + \{F \mapsto \lambda\overline{x_k}.(t[\theta_1 r_1]_{q_2})\}$$

      Thus we have

$$t/q_2 = (\theta_2(F(\overline{x_k})))/q_2 = (\theta_2(l_2/q_1))/q_2 = ((\theta_2 l_2)/q_1)/q_2 = (\theta_2 l_2)/q = \theta_1 l_1$$

      and hence $\theta_2 \overset{=}{\to} \theta_2'$. Theorem 3.9 yields $\theta_2 r_2 \to^* \theta_2' r_2$.
      Let H be a new variable (unused so far in this context) and

$$\begin{array}{rcl} \theta_0 & := & \theta_2 \cup \{H \mapsto \theta_2'(F)\} \\ \theta_0' & := & \theta_0 + \{F \mapsto \theta_2'(F)\} \end{array}$$

      and $l_0 := l_2[H(\overline{x_k})]_{q_1}$. From $\theta_2 \overset{=}{\to} \theta_2'$ is follows that $\theta_0 \overset{=}{\to} \theta_0'$. Applying Theorem 3.9 we get $(\theta_2 l_2)[\theta_1 r_1]_q = (\theta_2 l_2)[\theta_2'(F(\overline{x_k}))]_{q_1} = \theta_0 l_0 \overset{*}{\to} \theta_0' l_0 = \theta_0' l_2 = \theta_2' l_2 = \theta_2' l_2 \vdash\!\!\to \theta_2' r_2$ and therefore

$$s_2/p_2 = \theta_2 r_2 \overset{*}{\to} \theta_2' r_2 \vdash\!\!\to \theta_2' l_2 \overset{*}{\leftarrow} (\theta_2 l_2)[\theta_1 r_1]_q = s_1/p_2$$

      Placing it in the context it follows that

$$\begin{array}{ccccccccc} s_2 & = & s[\theta_2 r_2]_{p_2} & & s[(\theta_2 l_2)[\theta_1 r_1]_q]_{p_2} & = & s[\theta_1 r_1]_{p_1} & = & s_1 \\ & & \downarrow_* & & \downarrow_* & & & & \\ & & s[\theta_2' r_2]_{p_2} & \vdash\!\!\to & s[\theta_2' l_2]_{p_2} & & & & \end{array}$$

      and hence $s_1 \overset{\sim}{\downarrow} s_2$.

      ii. The two redexes overlap, i.e. $q \in Pos(l_2)$ and l_2/q is not of the form $F(\ldots)$. W.l.o.g. assume that $bv(l_2) \cap Cod(\theta_2) = \{\}$. Thus it follows from Lemma 4.4 that there exist a critical pair $\langle u_1, u_2\rangle$ and a substitution δ, such that $\delta u_1 = \theta_2 r_2$ and $\delta u_2 = \theta_2(l_2)[\theta_1 r_1]_q$. By Definition 5.7 $\langle u_1, u_2\rangle$ is a critical pair of $\mathcal{E}/R$. By assumption there exist terms u_1', u_2', such that $u_1 \overset{*}{\to} u_1' \sim u_2' \overset{*}{\leftarrow} u_2$. From Theorem 3.9 it follows that $\delta u_i \to^* \delta u_i'$, $i = 1, 2$. As $\sim$ is defined by a symmetric PRS, Theorem 3.9 also yields $\delta u_1' \sim \delta u_2'$. So we have $s_2 = s[\delta u_1]_{p_2} \overset{*}{\to} s[\delta u_1']_{p_2} \sim s[\delta u_2']_{p_2} \overset{*}{\leftarrow} s[\delta u_2]_{p_2} = s_1$ and hence $s_1 \overset{\sim}{\downarrow} s_2$.

(c) The last case is $p_1 \leq p_2$ with $q := p_2/p_1$. This case is similar to case 2b, except that we have to make use of the condition that R is left linear. There are two cases:

i. If the two redexes do not overlap, we again have $\theta_1(F) = \lambda\overline{x_k}.t$ and define

$$\theta_1' := \theta_1 + \{F \mapsto \lambda\overline{x_k}.(t[\theta_2 r_2]_{q_2})\}$$

So we get $\theta_1 \stackrel{=}{\vdash\!\dashv} \theta_1'$ and Theorem 3.9 yields $\theta_1 r_1 \stackrel{*}{\vdash\!\dashv} \theta_1' r_1$. As the PRS R is assumed to be left-linear, the free variable F occurs only once in l_1. Therefore

$$(\theta_1 l_1)[\theta_2 r_2]_q = (\theta_1 l_1)[\theta_1'(F(\overline{x_k}))]_{q_1} = \theta_1' l_1 \to \theta_1' r_1$$

It follows that

$$\begin{array}{ccccccccc} s_1 & = & s[\theta_1 r_1]_{p_1} & & s[(\theta_1 l_1)[\theta_2 r_2]_q]_{p_1} & = & s[\theta_2 r_2]_{p_2} & = & s_2 \\ & & \downarrow_* & & \downarrow & & & & \\ & & s[\theta_1 r_1]_{p_1} & \sim & s[\theta_1' r_1]_{p_1} & & & & \end{array}$$

and hence $s_1 \stackrel{\sim}{\downarrow} s_2$.

ii. The case where the two redexes overlap, i.e. $q \in Pos(l_1)$ and l_1/q is not of the form $F(\ldots)$ is completely analogous to case 2(b)ii.

□

Huet gives a simple example which shows that left-linearity of R is essential.

With the help of these lemmas it is now possible to formulate a sufficient criterion for the confluence of an equational PRS.

Theorem 5.11 *Let $\langle R, \mathcal{E}\rangle$ be an equational PRS, such that R is left-linear and $(\to \cdot \sim)$ terminates. Then the equational PRS $\langle R, \mathcal{E}\rangle$ is confluent iff $u_1{\downarrow} \sim u_2{\downarrow}$ for all critical pairs $\langle u_1, u_2\rangle$ of $\langle R, \mathcal{E}\rangle$, where $u_i{\downarrow}$ is an arbitrary $\to$-normal form of u_i.*

Proof First note that since $\to \cdot \sim$ terminates, so does $\to$ because $\sim$ is reflexive. Hence the notation $t{\downarrow}$ is always defined. The theorem follows almost directly from 5.4, 5.9 and 5.10 because $u_1 \stackrel{\sim}{\downarrow} u_2 \Leftrightarrow u_1{\downarrow} \sim u_2{\downarrow}$: the $\Leftarrow$-direction is trivial; for the other direction note that if $u_1 \stackrel{*}{\to} u_1' \sim u_2' \stackrel{*}{\leftarrow} u_2$ then confluence implies $u_1{\downarrow} \sim u_2{\downarrow}$ using Lemma 5.3. □

Example 5.12 Now we can prove that the PRS R from Example 5.1 is confluent modulo the symmetric PRS

$$\mathcal{E} := \{\mathsf{Q}x.\mathsf{Q}y.H(x,y) \leftrightarrow \mathsf{Q}y.\mathsf{Q}x.H(x,y) \mid \mathsf{Q} \in \{\forall, \exists\}\}$$

As usual, $\sim$ denotes the equivalence relation defined by $\mathcal{E}$. It is easily checked that all critical pairs of R arise by overlapping $\mathsf{Q}*$ with $*\mathsf{Q}$, and that their two normal forms are $\langle r{\downarrow}, s{\downarrow}\rangle = \langle \mathsf{Q}x.\mathsf{Q}y.(P'(x) * Q'(y)), \mathsf{Q}y.\mathsf{Q}x.(P'(x) * Q'(y))\rangle$. Thus we have $r{\downarrow} \sim s{\downarrow}$.

In addition we can overlap the rules $\mathsf{Q}*$ and $*\mathsf{Q}$ with the rules in $\mathcal{E}$ which gives rise to the critical pairs of $\mathcal{E}/R$, whose normal forms are $\langle \mathsf{Q}x.\mathsf{Q}y.(H(x,y) * Q), \mathsf{Q}y.\mathsf{Q}x.(H(x,y) * Q)\rangle$ and $\langle \mathsf{Q}x.\mathsf{Q}y.(Q * H(x,y)), \mathsf{Q}y.\mathsf{Q}x.(Q * H(x,y))\rangle$, both of which are contained in $\sim$.

As R is left-linear and $(\to \cdot \sim)$ terminates, it follows from Theorem 5.11 that $\langle R, \mathcal{E}\rangle$ is a confluent equational PRS: modulo quantifier-commutativity, R computes a unique prenex normal form. As $=_{\mathcal{E}}$ is decidable the relation $=_{R \cup \mathcal{E}}$ is decidable by Lemma 5.3.

It is interesting to note that confluence is destroyed by a frequently employed optimization in computing prenex forms:

$$\begin{array}{rcl} (\forall x.P'(x)) \wedge (\forall y.Q'(y)) & \to & \forall x.(P'(x) \wedge Q'(x)) \\ (\exists x.P'(x)) \vee (\exists y.Q'(y)) & \to & \exists x.(P'(x) \vee Q'(x)) \end{array}$$

These new rules give rise to non-trivial critical pairs with R, requiring, for example, the further rule $\forall x.\forall y.(P'(x) \wedge Q'(y)) \to \forall x.(P'(x) \wedge Q'(x))$. It seems unlikely that confluence can be regained by some form of completion.

6 Orthogonal Pattern Rewrite Systems

We now turn our attention to a subclass of PRSs, the so called orthogonal ones. An **Orthogonal Pattern Rewrite System** (**OPRS**) is a PRS that is left linear and has no critical pairs. This means that there are no rules whose left-hand sides overlap (see Definition 4.1).

Orthogonal term-rewriting systems have a long history [28, 12, 17]. They have been studied very closely because of their similarity to functional programs with pattern matching. The key property of orthogonal systems is their confluence, regardless of whether they terminate or not. We show that this holds for OPRSs as well. The main idea is to define a relation $\geqslant$ on terms such that $\rightarrow \subseteq \geqslant \subseteq \overset{*}{\rightarrow}$, which implies $\geqslant^* = \overset{*}{\rightarrow}$. It is well known that in this case $\rightarrow$ is confluent if $\geqslant$ has the **diamond property**: $r \geqslant s \ \wedge \ r \geqslant t \ \Rightarrow \ \exists u.\, s \geqslant u \ \wedge \ t \geqslant u$.

6.1 The Classical Proof

In this section we generalize Aczel's [1] confluence proof from his "consistent sets of contraction schemes" to arbitrary OPRSs. Note that the former are a proper subset of the latter. The proof proceeds roughly like the one for the untyped λ-calculus due to Tait and Martin-Löf [3]. Although we want to prove the confluence of OPRSs, the first steps towards the standard proof work just as well for HRSs.

Given a fixed HRS R, **parallel reduction** w.r.t. R is the smallest relation $\geqslant$ on terms which is closed under the following inference rules:

$$\frac{s_i \geqslant t_i \quad (i = 1, \ldots, n)}{a(\overline{s_n}) \geqslant a(\overline{t_n})} \ (\mathrm{A}) \qquad \frac{s \geqslant t}{\lambda x.s \geqslant \lambda x.t} \ (\mathrm{L})$$

$$\frac{s_i \geqslant t_i \quad (i = 1, \ldots, n) \quad c(\overline{t_n}) = \theta l \quad (l \rightarrow r) \in R}{c(\overline{s_n}) \geqslant \theta r} \ (\mathrm{R})$$

where a is an atom of type $\overline{\tau_n} \rightarrow \tau$ and $s_i : \tau_i$. Our relation $\geqslant$ is essentially Aczel's $>$. It is instructive to look at a few variations on this theme:

- For orthogonal TRSs, (L) is dropped, and (R) becomes $\theta l \geqslant \theta r$.
- For pure λ-calculus, (A) becomes $s_0 \geqslant t_0 \wedge s_1 \geqslant t_1 \ \Rightarrow \ (s_0 \ s_1) \geqslant (t_0 \ t_1)$, (R) becomes $s \geqslant s' \wedge t \geqslant t' \ \Rightarrow \ (\lambda x.s)t \geqslant \{x \mapsto t'\}(s')$, and we need to add $a \geqslant a$. The latter is a special case of the above formulation of (A).
- For OPRSs, Nipkow [27] uses an apparently weaker version of (R) which does not allow overlapping reductions: $(\forall F \in fv(l).\, \theta(F) \geqslant \theta'(F)) \ \Rightarrow \ \theta l \geqslant \theta' r$. Note that for OPRSs the two versions of (R) coincide because left-hand sides do not overlap. Nevertheless it seems that by using the stronger form above, the confluence proof is simplified.

Further variations of this technique appear in the literature [39, 6].

Parallel reduction has a number of interesting properties.

Lemma 6.1 *$s \geqslant s$ holds for all terms s in long $\beta\eta$-normal form.*

Proof by induction on the structure of s. □

Because all rules are of base type we again have

Lemma 6.2 *If $\lambda x.s \geqslant t'$ then $t' = \lambda x.t$ and $s \geqslant t$ for some t.*

More importantly we find that $\rightarrow$ and $\geqslant$ are strongly related:

Lemma 6.3 $\rightarrow \subseteq \geqslant \subseteq \stackrel{*}{\rightarrow}$

Proof using the inductive definition of $\rightarrow$ (Definition 3.6).

- $s \rightarrow t \;\Rightarrow\; s \geqslant t$ is proved by induction on the structure of $s \rightarrow t$. If $\theta l \rightarrow \theta r$ then $l = c(\overline{l_n})$ and Lemma 6.1 implies $\theta l_i \geqslant \theta l_i$ and thus (R) yields $\theta l \geqslant \theta r$. If $a(\overline{s_n}) \rightarrow a(\overline{t_n})$, where $s_k \rightarrow t_k$ and $s_i = t_i$ for all $i \neq k$, then $s_i \geqslant t_i$ for all i by induction hypothesis together with Lemma 6.1. Hence $a(\overline{s_n}) \geqslant a(\overline{t_n})$ follows by rule (A). The remaining case is trivial.
- $s \geqslant t \;\Rightarrow\; s \stackrel{*}{\rightarrow} t$ is proved by induction on the structure of $s \geqslant t$. If $c(\overline{s_n}) \geqslant \theta r$ by rule (R), then $s_i \stackrel{*}{\rightarrow} t_i$ follows by induction hypothesis and hence $c(\overline{s_n}) \stackrel{*}{\rightarrow} c(\overline{t_n}) = \theta l \rightarrow \theta r$. If $a(\overline{s_n}) \geqslant a(\overline{t_n})$ by rule (A), $s_i \stackrel{*}{\rightarrow} t_i$ follows by induction hypothesis and hence $a(\overline{s_n}) \stackrel{*}{\rightarrow} a(\overline{t_n})$. The remaining case is trivial. □

Next we show that $\geqslant$ interacts very nicely with substitutions. The proof is similar to the one of Theorem 3.9 but considerably simpler.

Lemma 6.4 *If $s \geqslant s'$ and $\theta \geqslant \theta'$ then $\theta s \geqslant \theta' s'$.*

Proof by induction on the order of θ (see Definition 2.1) with a nested induction on the structure of $s \geqslant s'$.

(A) If $s = a(\overline{s_n}) \geqslant a(\overline{s'_n}) = s'$, then by the inner induction hypothesis $\theta s_i \geqslant \theta' s'_i$. We distinguish two cases.

1. If $a \notin \mathcal{D}om(\theta)$ (and hence $a \notin \mathcal{D}om(\theta')$) then $\theta s = a(\overline{\theta s_n}) \geqslant a(\overline{\theta' s'_n}) = \theta' s'$ follows by rule (A).
2. If $a \in \mathcal{D}om(\theta)$ then $\theta a = \lambda\overline{y_n}.t$. By Lemma 6.2 it follows that $\theta' a = \lambda\overline{y_n}.t'$ where $t \geqslant t'$. Define the substitutions $\delta = \{\overline{y_n \mapsto \theta s_n}\}$ and $\delta' = \{\overline{y_n \mapsto \theta' s'_n}\}$ and notice that we have $\delta \geqslant \delta'$. If a is of type $\overline{\tau_n} \rightarrow \tau$, the definition of ord implies $ord(\tau_i) < ord(\overline{\tau_n} \rightarrow \tau)$ and hence $ord(\delta) < ord(\delta')$ (note that this also holds in case $n = 0$). Thus the outer induction hypothesis applies: $\delta t \geqslant \delta' t'$ because $t \geqslant t'$. Thus we obtain: $\theta s = (\theta a)(\overline{\theta s_n}) = \delta t \geqslant \delta' t' = (\theta' a)(\overline{\theta' s'_n}) = \theta' s'$.

(L) If $s = \lambda x.t$, $s' = \lambda x.t'$ and $t \geqslant t'$ then the inner induction hypothesis yields $\theta s = \lambda x.(\theta t) \geqslant \lambda x.(\theta' t') = \theta' s'$ using rule (L).

(R) If $s = c(\overline{s_n})$, $s_i \geqslant s'_i$, $c(\overline{s'_n}) = \delta l$ and $s' = \delta r$ then the inner induction hypothesis implies $\theta s_i \geqslant \theta' s'_i$. Since $c(\overline{\theta' s'_n}) = \theta' \delta l$ rule (R) directly yields $\theta s = c(\overline{\theta s_n}) \geqslant \theta' \delta r = \theta' s'$. □

The following lemma expresses a simple idea: in a reduction step $\theta l \geqslant s$, where l is a linear pattern and does not overlap with any rule, the l-part cannot change, i.e. all reductions must take place inside the terms introduced via θ.

Lemma 6.5 *Let R be an OPRS and let $l_0 = \lambda\overline{x_n}.l$ be a linear pattern that does not overlap any left-hand side of R. If $\theta l \geqslant s$ and $\mathcal{C}od(\theta) \cap \{\overline{x_n}\} = \{\}$ ($\mathcal{D}om(\theta) \cap \{\overline{x_n}\} = \{\}$ by convention!) then there exists a substitution θ' such that $\theta' l = s$, $\theta|_{fv(l_0)} \geqslant \theta'$ and $\mathcal{D}om(\theta') = fv(l_0)$.*

Proof by induction on the structure of l.

1. If $l = c(\overline{l_m})$, then the last inference in $\theta l \geqslant s$ must be (A) or (R). In either case there are t_i such that $\theta l_i \geqslant t_i$. Each $\lambda\overline{x_n}.l_i$ is again a linear pattern. Since l_0 does not overlap any left-hand side of R, it follows easily from Corollary 4.5 that neither do the $\lambda\overline{x_n}.l_i$. Now the induction hypothesis yields substitutions θ_i such that $\theta_i l_i = t_i$, $\theta|_{fv(\lambda\overline{x_n}.l_i)} \geqslant \theta_i$ and $\mathcal{D}om(\theta_i) = fv(\lambda\overline{x_n}.l_i)$. Now let $\theta' := \bigcup_{i=1}^{m} \theta_i$, which is a well-defined substitution because the $\mathcal{D}om(\theta_i)$ are disjoint, thanks to linearity. In particular we have $\theta' l = c(\overline{t_m})$, $\theta|_{fv(l_0)} \geqslant \theta'$

and $\mathcal{D}om(\theta') = fv(l_0)$. If rule (A) was used, $\theta' l = s$ as required. Rule (R) cannot have been used because it would mean that $c(\overline{t_m}) = \delta l'$, where l' is the left-hand side of a rule in R. Because $\theta' l = \delta l'$, Corollary 4.5 implies that l_0 overlaps l', a contradiction.

2. If $l = F(\overline{s_m})$ then $l{\downarrow_\eta} = F(\overline{y_m})$ because l is a pattern. Wlog $\theta F = \lambda\overline{y_m}.r$. Hence $\theta l = (\lambda\overline{y_m}.r)(\overline{y_m}){\downarrow_\beta^\eta} = r$ and thus $r \geqslant s$. Let $\theta' = \{F \mapsto \lambda\overline{y_m}.s\}$. Obviously θ' has the desired properties.

3. If $l = \lambda x.l'$ then the claim follows easily from the induction hypothesis. (At this point it becomes important not simply to drop the λx because the remaining l' might no longer be a pattern.) □

Lemma 6.6 *Let R be an OPRS and let l be the left-hand side of a rule in R. If $\theta l = a(\overline{s_n})$ and $s_i \geqslant t_i$ then there exists a θ' such that $\theta' l = a(\overline{t_n})$ and $\theta \geqslant \theta'$.*

Proof l must be of the form $a(\overline{l_n})$ and a must be a constant. Since R is orthogonal, none of the l_i, all of which are patterns, can overlap with any left-hand side of R. By Lemma 6.5 we obtain substitutions θ_i such that $\theta_i l_i = t_i$, $\mathcal{D}om(\theta_i) = fv(l_i)$ and $\theta|_{fv(l_i)} \geqslant \theta_i$. Because l is linear, the θ_i have disjoint domains and $\theta'' := \bigcup_{i=1}^n \theta_i$ is well-defined, $\theta'' l = a(\overline{t_n})$ and $\theta|_{fv(l)} \geqslant \theta''$. Using Lemma 6.1 it is trivial to extend θ'' to θ' with the desired properties. □

As a corollary we easily obtain

Corollary 6.7 (Coherence) *Let R be an OPRS. If $(l \to r) \in R$, $\theta l = a(\overline{s_n})$ and $s_i \geqslant t_i$, $i = 1, \ldots, n$, then there exists a θ' such that $\theta' l = a(\overline{t_n})$ and $\theta r \geqslant \theta' r$.*

We can finally show that $\geqslant$ has the diamond property, i.e. if $s \geqslant t_i$, $i = 0, 1$, then there exists a u such that $t_i \geqslant u$, $i = 0, 1$.

Theorem 6.8 *If R is an OPRS then $\geqslant$ has the diamond property.*

Proof We assume that $s \geqslant s_i$, $i = 0, 1$, and show by induction on the structure of $s \geqslant s_0$ that there is a t such that $s_i \geqslant t$, $i = 0, 1$.

(L) If $s = \lambda x.u \geqslant \lambda x.u_0 = s_0$ and $u \geqslant u_0$, then Lemma 6.2 implies $s_1 = \lambda x.u_1$ and $u \geqslant u_1$. By induction hypothesis there exists a u such that $u_i \geqslant u$ and hence $s_i \geqslant \lambda x.u =: t$ by (L).

(A) If $s = a(\overline{u_n})$, $u_j \geqslant u_{0j}$, and $a(\overline{u_{0n}}) = s_0$, then $s \geqslant s_1$ can only be a consequence of (A) or (R). In either case $u_j \geqslant u_{1j}$ and hence by induction hypothesis there are t_j such that $u_{ij} \geqslant t_j$. If $s \geqslant s_1$ by (A) then $s_1 = a(\overline{u_{1n}})$ and thus $t := a(\overline{t_n})$ closes the diamond.

If $s \geqslant s_1$ by (R) then $a(\overline{u_{1n}}) = \theta l \to \theta r = s_1$ for suitable θ and $(l \to r) \in R$. Coherence yields θ' such that $a(\overline{t_n}) = \theta' l$ and $s_1 = \theta r \geqslant \theta' r =: t$. By rule (R) we also have $s_0 = a(\overline{u_{1n}}) \geqslant t$, thus closing the diamond.

(R) If $s = a(\overline{u_n})$, $u_j \geqslant u_{0j}$ and $a(\overline{u_{0n}}) = \theta l \to \theta r = s_0$ then $s \geqslant s_1$ can only be a consequence of (A) or (R). In either case $u_j \geqslant u_{1j}$ and hence by induction hypothesis there are t_j such that $u_{ij} \geqslant t_j$. Coherence yields θ' such that $a(\overline{t_n}) = \theta' l$ and $s_0 = \theta r \geqslant \theta' r =: t$. By rule (R) we also have $a(\overline{u_{1n}}) \geqslant t$. If $s \geqslant s_1$ by (A) then $s_1 = a(\overline{u_{1n}})$, thus closing the diamond.

If $s \geqslant s_1$ by (R) then $a(\overline{u_{1n}}) = \theta_1 l_1 \to \theta_1 r_1 = s_1$ for suitable θ_1 and $(l_1 \to r_1) \in R$. Coherence yields θ_1' such that $a(\overline{t_n}) = \theta_1' l_1$ and $\theta_1 r_1 \geqslant \theta_1' r_1$. Therefore $\theta' l = \theta_1' l_1$, i.e. l and l_1 overlap at ε. Because R is orthogonal this means $(l \to r) = (l_1 \to r_1)$, $\theta' = \theta_1'$ and hence $s_1 \geqslant \theta_1' r_1 = \theta' r = t$. □

6.2 Confluence by Complete Superdevelopments

This proof is inspired by Takahashi's proof of the confluence of semi-orthogonal CLC (conditional lambda calculus) [40] (see also Section 7). Takahashi uses *developments*, i.e. chains of reductions where no newly created redexes are contracted, to transform terms t into "normal forms" t^* where all redexes in t have been contracted. Her key idea is to show that if $t \geq t'$ then $t' \geq t^*$, where $\geq$ is the standard notion of parallel reduction instead of Aczel's $\geqslant$.

In the sequel we recast her work in the context of OPRSs using $\geqslant$. Thus the transformation from t to t^* is not a development, but is more like a superdevelopment defined by van Raamsdonk [37] for λ-calculus. We call the transformation $t \geqslant t^*$ a **complete superdevelopment**. Although the classical proof and Takahashi's version share the basic lemmas, we find that her auxiliary notion t^* leads to a shorter and more appealing proof of her main lemma (Lemma 6.10) compared to the direct proof of Theorem 6.8. Both proofs are shown to allow the reader a direct comparison.

Definition 6.9 Let R be an OPRS. For every λ-term t in long $\beta\eta$-normal form the term t^* is defined recursively as follows.

1. $(\lambda x.t)^* = \lambda x.(t^*)$
2. $a(\overline{t_n})^* = a(\overline{t_n{}^*})$, if $a(\overline{t_n{}^*})$ is not a redex.
3. $a(\overline{t_n})^* = \theta(r)$, if there is a rule $(l \to r) \in R$ and a substitution θ, such that $\theta(l) = a(\overline{t_n{}^*})$.

where a is an atom of type $\overline{\tau_n} \to \tau$ and $t_i : \tau_i$. The term t^* is well defined, because for OPRSs the rule $(l \to r)$ and the substitution θ are uniquely determined by the redex $a(\overline{t_n{}^*})$.

Lemma 6.10 *Let R be an OPRS, $\geqslant$ the corresponding parallel reduction and t a λ-term in long $\beta\eta$-normal form. Then we have $t \geqslant t' \;\Rightarrow\; t' \geqslant t^*$*

Proof by induction on the size of t. There are three cases:

(L) $t = \lambda x.s \geqslant \lambda x.s' = t'$ with $s \geqslant s'$. By induction hypothesis $s' \geqslant s^*$ and hence $t' = \lambda x.s' \geqslant \lambda x.s^* = t^*$.

(A) $t = a(\overline{t_n}) \geqslant a(\overline{t'_n}) = t'$ with $t_i \geqslant t'_i$ $(i = 1, \ldots, n)$. By induction hypothesis we have $t'_i \geqslant t^*_i$ $(i = 1, \ldots, n)$. Now there are two cases:

1. If $a(\overline{t^*_n})$ is no redex, i.e. there are no $(l \to r) \in R$ and θ such that $\theta l = a(\overline{t^*_n})$, then $t' = a(\overline{t'_n}) \geqslant a(\overline{t^*_n}) = t^*$.
2. If $a(\overline{t^*_n})$ is a redex, i.e. there are $(l \to r) \in R$ and θ such that $\theta(l) = a(\overline{t^*_n})$, then $t' = a(\overline{t'_n}) \geqslant \theta(r) = t^*$.

(R) $t = a(\overline{t_n}) \geqslant \theta(r)$ for some substitution θ and $(l \to r) \in R$ such that $t_i \geqslant t'_i$ $(i = 1, \ldots, n)$ and $\theta(l) = a(\overline{t'_n})$. By induction hypothesis we have $t'_i \geqslant t^*_i$. It follows from Lemma 6.6 that there is a substitution θ', such that $\theta'(l) = a(\overline{t^*_n})$ and $\theta \geqslant \theta'$. Lemma 6.4 yields $t' = \theta(r) \geqslant \theta'(r) = t^*$. □

Theorem 6.11 *OPRSs are confluent.*

Proof It follows from Lemma 6.10 that for any OPRS R the relation $\geqslant$ has the diamond property. Hence $\to$ is confluent, because of Lemma 6.3. □

7 Related Work

As already indicated in the introduction, PRSs are closely related to CRSs [16, 18]. Confluence of CRSs has been investigated for orthogonal systems. HRSs are the same as Wolfram's higher-order term rewriting systems. This abundance of slightly different frameworks has lead to a notion of higher-order rewriting system (HORS) which is parameterized by a "substitution calculus" [31, 29] and generalizes all of the aforementioned frameworks. In the case of HRSs/PRSs the substitution calculus is the simply-typed λ-calculus. It has been shown that all *weakly orthogonal* HORSs are confluent [31, 29]. Although the notion of weak orthogonality for HORSs is defined directly rather than in terms of critical pairs, it can be translated as follows:

Definition 7.1 A PRS R is called **weakly orthogonal** iff it is left-linear and all of its critical pairs are of the form $\langle u, u\rangle$.

A direct proof of confluence for all weakly orthogonal PRSs is given by van Raamsdonk [38]. This generalizes one of the results obtained in our paper, but at a considerable increase in complexity. Hence we believe that the simplified proofs of confluence for OPRSs which we provide have their own merit. On the other hand, van Oostrom's techniques yield further dividends, for example that the weakly-orthogonal combination of left-linear and confluent PRSs is again confluent [29, Thm 3.5.13], generalizing a theorem by Nipkow [27, Thm. 6.1].

This result about weakly-orthogonal systems has some interesting consequences. For example, it implies that lambda-calculus with both *beta* and *eta* (Example 4.10) is confluent: both rules are left-linear and all critical pairs are of the from $\langle u, u\rangle$.

Takahashi [40] has investigated a condition called **semi-orthogonality** which lies in between orthogonality and weak orthogonality: it is strictly weaker than orthogonality but might coincide with weak orthogonality. Takahashi proves confluence of semi-orthogonal "conditional lambda-calculi" (CLC), her own brand of higher-order rewrite systems. As CLC are very close to PRSs, semi-orthogonality can be defined for PRSs in the same way, and her confluence result carries over [22]. It turns out that one of her requirements, namely that the left-hand sides of two different rules do not overlap at position ϵ, is superfluous.

Finally there is a large body of research that is concerned with the combination of λ-calculi and rewrite systems (see, for example, [2]). Although superficially similar to our approach, it is in fact quite different: whereas we consider rewriting modulo the conversions of the λ-calculus, i.e. λ-calculus is a meta-language for describing rewrite systems, they combine β-reduction with other restricted forms of rewrite rules on the same level. This yields relatively strong modularity results for special combinations, e.g. adding β-reduction to a left-linear confluent TRS preserves confluence [24], whereas HRSs aim for a general theory of arbitrary higher-order rules.

Finally it should be mentioned that methods for proving termination of HRSs/PRSs are only just emerging [34, 35, 21, 14, 13]. More work is needed in this area.

Acknowledgment This paper has benefitted enormously from the amazing scrutiny of Ralph Matthes who was volunteered to present very preliminary fragments of it in a seminar.
