ABSTRACT. Language-integrated query is a powerful programming construct allowing database queries and ordinary program code to interoperate seamlessly and safely. Language-integrated query techniques rely on classical results about monadic comprehension calculi, including the *conservativity theorem* for nested relational calculus. Conservativity implies that query expressions can freely use nesting and unnesting, yet as long as the query result type is a flat relation, these capabilities do not lead to an increase in expressiveness over flat relational queries. Wong showed how such queries can be translated to SQL via a constructive rewriting algorithm, and Cooper and others advocated *higher-order* nested relational calculi as a basis for language-integrated queries in functional languages such as Links and F#. However there is no published proof of the central *strong normalization* property for higher-order nested relational queries: a previous proof attempt does not deal correctly with rewrite rules that duplicate subterms. This paper fills the gap in the literature, explaining the difficulty with a previous proof attempt, and showing how to extend the TT -*lifting* approach of Lindley and Stark to accommodate duplicating rewrites. We also show how to extend the proof to a recently-introduced calculus for *heterogeneous* queries mixing set and multiset semantics.

1. INTRODUCTION

The nested relational calculus [BNTW95] provides a principled foundation for integrating database queries into programming languages. Wong’s conservativity theorem [Won96] generalized the classic flat-flat theorem [PG92] to show that for any nesting depth d , a query expression over flat input tables returning collections of depth at most d can be expressed without constructing intermediate results of nesting depth greater than d . In the special case $d = 1$, this implies the flat-flat theorem, namely that a nested relational query mapping flat tables to flat tables can be expressed equivalently using the flat relational calculus. In addition, Wong’s proof technique was constructive, and gave an easily-implemented terminating rewriting algorithm for normalizing NRC queries to equivalent flat queries; these normal forms correspond closely to idiomatic SQL queries and translating from the former to the latter is straightforward. The basic approach has been extended in a number of

Key words and phrases: Strong normalization, TT -lifting, Nested relational calculus, Language-integrated query.

directions, including to allow for (nonrecursive) higher-order functions in queries [Coo09b], and to allow for translating queries that return nested results to a bounded number of flat relational queries [CLW14].

Normalization-based techniques are used in language-integrated query systems such as Kleisli [Won00] and Links [CLWY07], and can improve both performance and reliability of language-integrated query in F# [CLW13]. However, most work on normalization considers *homogeneous* queries in which there is a single collection type (e.g. homogeneous sets or multisets). Currently, language-integrated query systems such as C# and F# [MBB06] support duplicate elimination via a `Distinct()` method, which is translated to SQL queries in an ad hoc way, and comes with no guarantees regarding completeness or expressiveness as far as we know, whereas Database-Supported Haskell (DSH) [UG15] supports duplicate elimination but gives all operations list semantics and relies on more sophisticated SQL:1999 features to accomplish this. Fegaras and Maier [FM00] propose optimization rules for a nested object-relational calculus with set and bag constructs but do not consider the problem of conservativity with respect to flat queries.

Recently, we considered a *heterogeneous* calculus for mixed set and bag queries [RC19], and conjectured that it too satisfies strong normalization and conservativity theorems. However, in attempting to extend Cooper’s proof of normalization we discovered a subtle problem, which makes the original proof incomplete.

Most techniques to prove the strong normalization property for higher-order languages employ logical relations; among these, the Girard-Tait *reducibility* relation is particularly influential: reducibility interprets types as certain sets of strongly normalizing terms enjoying desirable closure properties with respect to reduction, called *candidates of reducibility* [GLT89]. The fundamental theorem then proves that every well-typed term is reducible, hence also strongly normalizing. In its traditional form, reducibility has a limitation that makes it difficult to apply it to certain calculi: the elimination form of every type is expected to be a *neutral* term or, informally, an expression that, when placed in an arbitrary evaluation context, does not interact with it by creating new redexes. However, some calculi possess *commuting conversions*, i.e. reduction rules that apply to nested elimination forms: such rules usually arise when the elimination form for a type (say, pairs) is constructed by means of an auxiliary term of any arbitrary, unrelated type. In this case, we expect nested elimination forms to commute; for example, we could have the following commuting conversion hoisting the elimination of pairs out of case analysis on disjoint unions:

$$\begin{aligned} & \text{cases } (\text{let } (a, b) = p \text{ in } t) \text{ of } \text{inl}(x) \Rightarrow u; \text{inr}(y) \Rightarrow v \\ & \rightsquigarrow \text{let } (a, b) = p \text{ in cases } t \text{ of } \text{inl}(x) \Rightarrow u; \text{inr}(y) \Rightarrow v \end{aligned}$$

where p has type $A \times B$, t has type $C + D$, u, v have type U , and the bound variables a, b are chosen fresh for u and v . Since in the presence of commuting conversions elimination forms are not neutral, a straightforward adaptation of reducibility to such languages is precluded.

1.1. $\top\top$ -lifting and NRC_λ . Cooper’s NRC_λ [Coo09a, Coo09b] extends the simply typed lambda calculus with collection types whose elimination form is expressed by *comprehensions* $\bigcup\{M|x \leftarrow N\}$, where M and N have a collection type, and the bound variable x can appear in M :

$$\frac{\Gamma \vdash N : \{S\} \quad \Gamma, x : S \vdash M : \{T\}}{\Gamma \vdash \bigcup\{M|x \leftarrow N\} : \{T\}}$$

(we use bold-style braces $\{\cdot\}$ to indicate collections as expressions or types of NRC_λ). In the rule above, we typecheck a comprehension destructuring collections of type $\{S\}$ to produce new collections in $\{T\}$, where T is an unrelated type: semantically, this corresponds to the union of all the collections $M[V/x]$, such that V is in N . According to the standard approach, we should attempt to define the reducibility predicate for the collection type $\{S\}$ as:

$$\text{Red}_{\{S\}} \triangleq \{N : \forall x, T, \forall M \in \text{Red}_{\{T\}}, \bigcup \{M|x \leftarrow N\} \in \text{Red}_{\{T\}}\}$$

(we use roman-style braces $\{\cdot\}$ to express metalinguistic sets). Of course the definition above is circular, since it uses reducibility over collections to express reducibility over collections; however, this inconvenience could in principle be circumvented by means of impredicativity, replacing $\text{Red}_{\{T\}}$ with a suitable, universally quantified candidate of reducibility (an approach we used in [RC17] in the context of justification logic). Unfortunately, the arbitrary return type of comprehensions is not the only problem: they are also involved in commuting conversions, such as:

$$\bigcup \{M|x \leftarrow \bigcup \{N|y \leftarrow P\}\} \rightsquigarrow \bigcup \{\bigcup \{M|x \leftarrow N\}|y \leftarrow P\} \quad (y \notin FV(M))$$

Because of this rule, comprehensions are not neutral terms, thus we cannot use the closure properties of candidates of reducibility (in particular, CR3 [GLT89]) to prove that a collection term is reducible. To address this problem, Lindley and Stark proposed a revised notion of reducibility based on a technique they called $\top\top$ -lifting [LS05]. $\top\top$ -lifting, which derives from Pitts's related notion of $\top\top$ -closure [Pit98], involves quantification over arbitrarily nested, reducible elimination contexts (*continuations*); the technique is actually composed of two steps: \top -lifting, used to define the set Red_T^\top of reducible continuations for collections of type T in terms of Red_T , and $\top\top$ -lifting proper, defining $\text{Red}_{\{T\}} = \text{Red}_T^{\top\top}$ in terms of Red_T^\top . In our setting, if we use \mathcal{SN} to denote the set of strongly normalizing terms, the two operations can be defined as follows:

$$\begin{aligned} \text{Red}_T^\top &\triangleq \{K : \forall M \in \text{Red}_T, K[\{M\}] \in \mathcal{SN}\} \\ \text{Red}_T^{\top\top} &\triangleq \{M : \forall K \in \text{Red}_T^\top, K[M] \in \mathcal{SN}\} \end{aligned}$$

Notice that, in order to avoid a circularity between the definitions of reducible collection continuations and reducible collections, the former are defined by lifting a reducible term M of type T to a singleton collection.

In NRC_λ , besides commuting conversions, we come across an additional problem concerning the property of distributivity of comprehensions over unions, represented by the following reduction rule:

$$\bigcup \{M \cup N|x \leftarrow P\} \rightsquigarrow \bigcup \{M|x \leftarrow P\} \cup \bigcup \{N|x \leftarrow P\}$$

One can immediately see that in $\bigcup \{M \cup N|x \leftarrow \square\}$ the reduction above duplicates the hole, producing a multi-hole context that is not a continuation in the Lindley-Stark sense.

Cooper, in his work, attempted to reconcile continuations with duplicating reductions. While considering extensions to his language, we discovered that his proof of strong normalization presents a nontrivial lacuna which we could only fix by relaxing the definition of continuations to allow multiple holes. This problem affected both the proof of the original result and our attempt to extend it, and has an avalanche effect on definitions and proofs, yielding a more radical revision of the $\top\top$ -lifting technique which is the subject of this paper.

The contribution of this paper is to place previous work on higher-order programming for language-integrated query on a solid foundation. As we will show, our approach also extends to proving normalization for a higher-order heterogeneous collection calculus $NRC_\lambda(Set, Bag)$ [RC19] and we believe our proof technique can be extended further.

This article is a revised and expanded version of a conference paper [RC20]. Compared with the conference paper, this article refines the notion of $\top\top$ -lifting by omitting a harmless, but unnecessary generalization, includes details of proofs that had to be left out, and expands the discussion of related work. In addition, we fully comment on the extension of our result to a language allowing to freely mix and compose set queries and bag queries, which was only marginally discussed in the conference version.

1.2. Summary. Section 2 reviews NRC_λ and its rewrite system. Section 3 presents the refined approach to reducibility needed to handle rewrite rules with branching continuations. Section 4 presents the proof of strong normalization for NRC_λ . Section 5 outlines the extension to a higher-order calculus $NRC_\lambda(Set, Bag)$ providing heterogeneous set and bag queries. Sections 6 and 7 discuss related work and conclude.

2. HIGHER-ORDER NRC

NRC_λ , a nested relational calculus with non-recursive higher-order functions, is defined by the following grammar:

$$\begin{array}{ll} \text{types} & S, T ::= A \mid S \rightarrow T \mid \langle \overline{\ell : \vec{T}} \rangle \mid \{T\} \\ \text{terms} & L, M, N ::= x \mid c(\vec{M}) \mid \langle \overline{\ell = \vec{M}} \rangle \mid M.\ell \mid \lambda x.M \mid (M \ N) \\ & \quad \mid \emptyset \mid \{M\} \mid M \cup N \mid \bigcup \{M \mid x \leftarrow N\} \\ & \quad \mid \text{empty } M \mid \text{where } M \text{ do } N \end{array}$$

Types include atomic types A, B, \dots (among which we have Booleans \mathbf{B}), record types with named fields $\langle \overline{\ell : \vec{T}} \rangle$, collections $\{T\}$; we define *relation types* as those in the form $\{\langle \overline{\ell : \vec{A}} \rangle\}$, i.e. collections of tuples of atomic types. Terms include applied constants $c(\vec{M})$, records with named fields and record projections $(\langle \overline{\ell = \vec{M}} \rangle, M.\ell)$, various collection terms (empty, singleton, union, and comprehension), the emptiness test **empty**, and one-sided conditional expressions for collection types **where** M **do** N . In this definition, x ranges over variable names, c over constants, and ℓ over record field names. We will allow ourselves to use sequences of generators in comprehensions, which are syntactic sugar for nested comprehensions, e.g.:

$$\bigcup \{M \mid x \leftarrow N, y \leftarrow R\} \triangleq \bigcup \{\bigcup \{M \mid y \leftarrow R\} \mid x \leftarrow N\}$$

The typing rules, shown in Figure 1, are largely standard, and we only mention those operators that are specific to our language: constants are typed according to a fixed signature Σ , prescribing the types of the n arguments and of the returned expression to be atomic; **empty** takes a collection and returns a Boolean indicating whether its argument is empty; **where** takes a Boolean condition and a collection and returns the second argument if the Boolean is true, otherwise the empty set. (Conventional two-way conditionals, at any type, are omitted for convenience but can be added without difficulty.)

$$\begin{array}{c}
\frac{x : T \in \Gamma}{\Gamma \vdash x : T} \quad \frac{\Sigma(c) = \vec{A}_n \rightarrow A' \quad (\Gamma \vdash M_i : A_i)_{i=1,\dots,n}}{\Gamma \vdash c(\vec{M}_n) : A'} \\
\\
\frac{(\Gamma \vdash M_i : T_i)_{i=1,\dots,n}}{\Gamma \vdash \langle \vec{\ell}_n = \vec{M}_n \rangle : \langle \vec{\ell}_n : \vec{T}_n \rangle} \quad \frac{\Gamma \vdash M : \langle \vec{\ell}_n : \vec{T}_n \rangle \quad i \in \{1, \dots, n\}}{\Gamma \vdash M.\ell_i : T_i} \\
\\
\frac{\Gamma, x : S \vdash M : T}{\Gamma \vdash \lambda x.M : S \rightarrow T} \quad \frac{\Gamma \vdash M : S \rightarrow T \quad \Gamma \vdash N : S}{\Gamma \vdash (M N) : T} \\
\\
\frac{}{\Gamma \vdash \emptyset : \{T\}} \quad \frac{\Gamma \vdash M : T}{\Gamma \vdash \{M\} : \{T\}} \quad \frac{\Gamma \vdash M : \{T\} \quad \Gamma \vdash N : \{T\}}{\Gamma \vdash M \cup N : \{T\}} \\
\\
\frac{\Gamma, x : T \vdash M : \{S\} \quad \Gamma \vdash N : \{T\}}{\Gamma \vdash \bigcup \{M | x \leftarrow N\} : \{S\}} \\
\\
\frac{\Gamma \vdash M : \{T\}}{\Gamma \vdash \text{empty } M : \mathbf{B}} \quad \frac{\Gamma \vdash M : \mathbf{B} \quad \Gamma \vdash N : \{T\}}{\Gamma \vdash \text{where } M \text{ do } N : \{T\}}
\end{array}$$

Figure 1: Type system of NRC_λ .

2.1. Reduction and normalization. NRC_λ is equipped with a rewrite system whose purpose is to convert expressions of flat relation type into a sublanguage isomorphic to a fragment of SQL, even when the original expression contains subterms whose type is not available in SQL, such as nested collections. The rules for this rewrite system are shown in Figure 2.

$$\begin{array}{l}
(\lambda x.M) N \rightsquigarrow M[N/x] \quad \langle \dots, \ell = M, \dots \rangle.\ell \rightsquigarrow M \quad c(\vec{V}) \rightsquigarrow \llbracket c \rrbracket(\vec{V}) \\
\\
\begin{array}{l}
\bigcup \{\emptyset | x \leftarrow M\} \rightsquigarrow \emptyset \quad \bigcup \{M | x \leftarrow \emptyset\} \rightsquigarrow \emptyset \quad \bigcup \{M | x \leftarrow \{N\}\} \rightsquigarrow M[N/x] \\
\bigcup \{M \cup N | x \leftarrow R\} \rightsquigarrow \bigcup \{M | x \leftarrow R\} \cup \bigcup \{N | x \leftarrow R\} \\
\bigcup \{M | x \leftarrow N \cup R\} \rightsquigarrow \bigcup \{M | x \leftarrow N\} \cup \bigcup \{M | x \leftarrow R\} \\
\bigcup \{M | y \leftarrow \bigcup \{R | x \leftarrow N\}\} \rightsquigarrow \bigcup \{M | x \leftarrow N, y \leftarrow R\} \quad (\text{if } x \notin \text{FV}(M)) \\
\bigcup \{M | x \leftarrow \text{where } N \text{ do } R\} \rightsquigarrow \text{where } N \text{ do } \bigcup \{M | x \leftarrow R\} \quad (\text{if } x \notin \text{FV}(M))
\end{array} \\
\\
\begin{array}{l}
\text{where true do } M \rightsquigarrow M \quad \text{where false do } M \rightsquigarrow \emptyset \quad \text{where } M \text{ do } \emptyset \rightsquigarrow \emptyset \\
\text{where } M \text{ do } (N \cup R) \rightsquigarrow (\text{where } M \text{ do } N) \cup (\text{where } M \text{ do } R) \\
\text{where } M \text{ do } \bigcup \{N | x \leftarrow R\} \rightsquigarrow \bigcup \{\text{where } M \text{ do } N | x \leftarrow R\} \\
\text{where } M \text{ do where } N \text{ do } R \rightsquigarrow \text{where } (M \wedge N) \text{ do } R \\
\text{empty } M \rightsquigarrow \text{empty } (\bigcup \{\langle \rangle | x \leftarrow M\}) \quad (\text{if } M \text{ is not relation-typed})
\end{array}
\end{array}$$

Figure 2: Query normalization

Reduction on applied constants can happen when all of the arguments are values in normal form, and relies on a fixed semantics $\llbracket \cdot \rrbracket$ which assigns to each constant c of signature $\Sigma(c) = \vec{A}_n \rightarrow A'$ a function mapping sequences of values of type \vec{A}_n to values of type A' . The rules for collections and conditionals are mostly standard. The reduction rule for the emptiness test is triggered when the argument M is not of relation type (but, for instance, of nested collection type) and employs comprehension to generate a (trivial) relation that is empty if and only if M is.

The normal forms of queries under these rewriting rules construct no intermediate nested structures, and are straightforward to translate to equivalent SQL queries. Cooper [Coo09b] and Lindley and Cheney [LC12] give details of such translations. Cheney et al. [CLW13] showed how to improve the performance and reliability of LINQ in F# using normalization and gave many examples showing how higher-order queries support a convenient, compositional language-integrated query programming style.

3. REDUCIBILITY WITH BRANCHING CONTINUATIONS

We introduce here the extension of $\top\top$ -lifting we use to derive a proof of strong normalization for NRC_λ . The main contribution of this section is a refined definition of continuations with branching structure and multiple holes, as opposed to the linear structure with a single hole used by standard $\top\top$ -lifting. In our definition, continuations (as well as the more general notion of context) are particular forms of terms: in this way, the notion of term reduction can be used for continuations as well, without need for auxiliary definitions.

3.1. Contexts and continuations. We start our discussion by introducing *contexts*, or terms with multiple, labelled holes that can be instantiated by plugging other terms (including other contexts) into them.

Definition 3.1 (context). Let us fix a countably infinite set \mathcal{P} of indices: a *context* C is a term that may contain distinguished free variables $[p]$, also called *holes*, where $p \in \mathcal{P}$.

Given a finite map from indices to terms $[p_1 \mapsto M_1, \dots, p_n \mapsto M_n]$ (*context instantiation*), the notation $C[p_1 \mapsto M_1, \dots, p_n \mapsto M_n]$ (*context application*) denotes the term obtained by simultaneously substituting M_1, \dots, M_n for the holes $[p_1], \dots, [p_n]$.

We will use metavariables η, θ to denote context instantiations.

Definition 3.2 (support). Given a context C , its *support* $\text{supp}(C)$ is defined as the set of the indices p such that $[p]$ occurs in C as a free variable:

$$\text{supp}(C) \triangleq \{p : [p] \in \text{FV}(C)\}$$

When a term does not contain any $[p]$, we say that it is a *pure* term; when it is important that a term be pure, we will refer to it by using overlined metavariables $\overline{L}, \overline{M}, \overline{N}, \overline{R}, \dots$. Under the appropriate assumptions, a multiple context instantiation can be decomposed.

Definition 3.3. An instantiation η is *permutable* iff for all $p \in \text{dom}(\eta)$ we have $\text{FV}(\eta(p)) \cap \text{dom}(\eta) = \emptyset$.

Lemma 3.4. Let η be permutable and let us denote by η_{-p} the restriction of η to indices other than p . Then for all $p \in \text{dom}(\eta)$ we have:

$$C\eta = C[p \mapsto \eta(p)]\eta_{-p} = C\eta_{-p}[p \mapsto \eta(p)]$$

We can now define continuations as certain contexts that capture how one or more collections can be used in a program.

Definition 3.5 (continuation). Continuations K are defined as the following subset of contexts:

$$K, H ::= [p] \mid \overline{M} \mid K \cup K \mid \bigcup \{\overline{M} \mid x \leftarrow K\} \mid \text{where } \overline{B} \text{ do } K$$

where for all indices p , $[p]$ can occur at most once.

This definition differs from the traditional one in two ways: first, holes are decorated with an index; secondly, and most importantly, the production $K \cup K$ allows continuations to branch and, as a consequence, to use more than one hole. Note that the grammar above is ambiguous, in the sense that certain expressions like $\text{where } \overline{B} \text{ do } \overline{N}$ can be obtained either from the production $\text{where } \overline{B} \text{ do } K$ with $K = \overline{N}$, or as pure terms by means of the production \overline{M} : we resolve this ambiguity by parsing these expressions as pure terms whenever possible, and as continuations only when they are proper continuations.

An additional complication of NRC_λ when compared to the computational metalanguage for which $\top\top$ -lifting was devised lies in the way conditional expressions can reduce when placed in an arbitrary context: continuations in the grammar above are not liberal enough to adapt to such reductions, therefore, like Cooper, we will need an additional definition of *auxiliary* continuations allowing holes to appear in the body of a comprehension (in addition to comprehension generators).

Definition 3.6 (auxiliary continuation). Auxiliary continuations are defined as the following subset of contexts:

$$Q, O ::= [p] \mid \overline{M} \mid Q \cup Q \mid \bigcup \{Q|x \leftarrow Q\} \mid \text{where } \overline{B} \text{ do } Q$$

where for all indices p , $[p]$ can occur at most once.

We can then see that regular continuations are a special case of auxiliary continuations; however, an auxiliary continuation is allowed to branch not only with unions, but also with comprehensions.¹

We use the following definition of *frames* to represent flat continuations with a distinguished hole.

Definition 3.7 (frame). Frames are defined by the following grammar:

$$F ::= \bigcup \{Q|x\} \mid \bigcup \{x \leftarrow Q\} \mid \text{where } \overline{B}$$

where for all indices p , $[p]$ can occur at most once.

The operation F^p , lifting a frame to an auxiliary continuation with a distinguished hole $[p]$ is defined by the following rules

$$\begin{aligned} \bigcup \{Q|x\}^p &= \bigcup \{Q|x \leftarrow [p]\} & (p \notin \text{supp}(Q)) \\ \bigcup \{x \leftarrow Q\}^p &= \bigcup \{[p] | x \leftarrow Q\} & (p \notin \text{supp}(Q)) \\ (\text{where } B)^p &= \text{where } B \text{ do } [p] \end{aligned}$$

The composition operation $Q \odot_p F$ is defined as:

$$Q \odot_p F = Q[p \mapsto F^p]$$

We generally use frames in conjunction with continuations or auxiliary continuations when we need to partially expose their leaves: for example, if we write $K = K_0 \odot_p \bigcup \{\overline{M}|x\}$, we know that instantiating K at index p with (for example) a singleton term will create a redex: $K[p \mapsto \{\overline{L}\}] \rightsquigarrow K_0[p \mapsto \overline{M} [\overline{L}/x]]$. We say that such a reduction is a *reduction at the interface* between the continuation and the instantiation.

¹It is worth noting that Cooper's original definition of auxiliary continuation does not use branching comprehension (nor branching unions), but is linear just like the original definition of continuation. The only difference between regular and auxiliary continuations in his work is that the latter allowed nesting not just within comprehension generators, but also within comprehension bodies (in our notation, this would correspond to two separate productions $\bigcup \{\overline{M}|x \leftarrow Q\}$ and $\bigcup \{Q|x \leftarrow \overline{N}\}$).

We introduce two measures $|\cdot|_p$ and $\|\cdot\|_p$ denoting the nesting depth of a hole $[p]$: the two measures differ in the treatment of nesting within the body of a comprehension.

Definition 3.8. The measures $|Q|_p$ and $\|Q\|_p$ are defined as follows:

$$\begin{aligned} |q|_p &= \|q\|_p = \begin{cases} 1 & \text{if } p = q \\ 0 & \text{else} \end{cases} \\ |\overline{M}|_p &= \|\overline{M}\|_p = 0 \\ |Q_1 \cup Q_2|_p &= \max(|Q_1|_p, |Q_2|_p) & \|Q_1 \cup Q_2\|_p &= \max(\|Q_1\|_p, \|Q_2\|_p) \\ \text{where } B \ Q|_p &= |Q|_p + 1 & \text{where } B \ Q\|_p &= \|Q\|_p + 1 \\ |\bigcup\{Q_1|x \mapsto Q_2\}|_p &= \begin{cases} |Q_1|_p & \text{if } p \in \text{supp}(Q_1) \\ |Q_2|_p + 1 & \text{if } p \in \text{supp}(Q_2) \\ 0 & \text{else} \end{cases} \\ \|\bigcup\{Q_1|x \mapsto Q_2\}\|_p &= \begin{cases} \|Q_1\|_p + 1 & \text{if } p \in \text{supp}(Q_1) \\ \|Q_2\|_p + 1 & \text{if } p \in \text{supp}(Q_2) \\ 0 & \text{else} \end{cases} \end{aligned}$$

We will also use $|Q|$ and $\|Q\|$ to refer to the derived measures:

$$|Q| = \sum_{p \in \text{supp}(Q)} |Q|_p \quad \|Q\| = \sum_{p \in \text{supp}(Q)} \|Q\|_p$$

NRC_λ reduction can be used immediately on contexts (including regular and auxiliary continuations) since these are simply terms with distinguished free variables; we will also abuse notation to allow ourselves to specify reduction on hole instantiations: whenever $\eta(p) \rightsquigarrow N$ and $\eta' = \eta_{\neg p}[p \mapsto N]$, we can write $\eta \rightsquigarrow \eta'$.

We will denote the set of strongly normalizing terms by \mathcal{SN} . Strongly-normalizing instantiated contexts satisfy the following property:

Lemma 3.9. *For all contexts C , terms N and indices p , if $C[p \mapsto N] \in \mathcal{SN}$, we have $C \in \mathcal{SN}$; if furthermore $p \in \text{supp}(C)$, then $N \in \mathcal{SN}$.*

For strongly normalizing terms (and by extension for hole instantiations containing only strongly normalizing terms), we can introduce the concept of maximal reduction length.

Definition 3.10 (maximal reduction length). Let $M \in \mathcal{SN}$: we define $\nu(M)$ as the maximum length of all reduction sequences starting with M . We also define $\nu(\eta)$ as $\sum_{p \in \text{dom}(\eta)} \nu(\eta(p))$, whenever this value is defined.

Since under plain reduction each term can be reduced only in a finite number of ways, it is easy to see that $\nu(M)$ is defined for any strongly normalizing term M . Furthermore, $\nu(M)$ is strictly decreasing under reduction.

Lemma 3.11. *For all strongly normalizing terms M , if $M \rightsquigarrow M'$, then $\nu(M') < \nu(M)$.*

Proof. If $\nu(M') \geq \nu(M)$, by pre-composing $M \rightsquigarrow M'$ with a reduction chain of maximal length starting at M' we obtain a new reduction chain starting at M with length strictly greater than $\nu(M)$; this contradicts the definition of $\nu(M)$. \square

Composing an (auxiliary) continuation with a frame does not decrease the maximal reduction length.

Lemma 3.12. *If $Q \oplus_p F \in \mathcal{SN}$, then $Q \in \mathcal{SN}$ and $\nu(Q) \leq \nu(Q \oplus_p F)$.*

Proof. By induction on the possible reduction sequences in Q , we show there exists a corresponding reduction sequence with the same length in $Q \oplus_p F$. \square

3.2. Renaming reduction. Reducing a plain or auxiliary continuation will yield a context that is not necessarily in the same class because certain holes may have been duplicated. For this reason, we introduce a refined notion of renaming reduction which we can use to rename holes in the results so that each of them occurs at most one time.

Definition 3.13. Given a term M with holes and a finite map $\sigma : \mathcal{P} \rightarrow \mathcal{P}$, we write $M\sigma$ for the term obtained from M by replacing each hole $[p]$ such that $\sigma(p)$ is defined with $[\sigma(p)]$.

Even though finite renaming maps are partial functions, it is convenient to extend them to total functions by taking $\sigma(p) = p$ whenever $p \notin \text{dom}(\sigma)$; we will write id to denote the empty renaming map, whose total extension is the identity function on \mathcal{P} .

Definition 3.14 (renaming reduction). M σ -reduces to N (notation: $M \xrightarrow{\sigma} N$) iff $M \rightsquigarrow N\sigma$.

Under renaming reduction, a term may be reduced in an infinite number of ways because, if $M \rightsquigarrow N$, there may be infinite R, σ such that $N = R\sigma$. Fortunately, we can prove that to every renaming reduction chain there corresponds a plain reduction chain of the same length, and vice-versa.

Lemma 3.15. *If $M \rightsquigarrow N$, then $M\sigma \rightsquigarrow N\sigma$.*

Proof. Routine induction on the derivation of $M \rightsquigarrow N$. \square

Lemma 3.16.

- (1) If $M \underbrace{\rightsquigarrow \dots \rightsquigarrow}_{n \text{ times}} N$, then $M \underbrace{\xrightarrow{\text{id}} \dots \xrightarrow{\text{id}}}_{n \text{ times}} N$
- (2) If $M \xrightarrow{\sigma_1} \dots \xrightarrow{\sigma_n} N$, then $M \underbrace{\rightsquigarrow \dots \rightsquigarrow}_{n \text{ times}} N\sigma_n \dots \sigma_1$

Proof. The first part of the lemma is trivial. For the second part, proceed by induction on the length of the reduction chain: in the inductive case, we have $M \xrightarrow{\sigma_1} \dots \xrightarrow{\sigma_n} M' \xrightarrow{\sigma_{n+1}} N$ by hypothesis and $M \rightsquigarrow \dots \rightsquigarrow M'\sigma_n \dots \sigma_1$ by induction hypothesis; to obtain the thesis, we only need to prove that

$$M'\sigma_n \dots \sigma_1 \rightsquigarrow N\sigma_{n+1} \dots \sigma_1$$

In order for this to be true, by Lemma 3.15, it is sufficient to show that $M' \rightsquigarrow N\sigma_{n+1}$; this is by definition equivalent to $M' \xrightarrow{\sigma_{n+1}} N$, which we know by hypothesis. \square

Corollary 3.17. *Suppose $M \in \mathcal{SN}$: if $M \xrightarrow{\sigma} M'$, then $\nu(M')$ is defined and $\nu(M') < \nu(M)$.*

Proof. By Lemma 3.16, for any plain reduction chain there exists a renaming reduction chain of the same length, and vice-versa. Thus, since plain reduction lowers the length of the maximal reduction chain (Lemma 3.11), the same holds for renaming reduction. \square

The results above prove that the set of strongly normalizing terms is the same under the two notions of reduction, thus $\nu(M)$ can be used to refer to the maximal length of reduction chains starting at M either with or without renaming.

Our goal is to describe the reduction of pure terms expressed in the form of instantiated continuations. One first difficulty we need to overcome is that, as we noted, the sets of continuations (both regular and auxiliary) are not closed under reduction; thankfully, we can prove they are closed under renaming reduction.

Lemma 3.18.

- (1) For all continuations K , if $K \rightsquigarrow C$, there exist a continuation K' and a finite map σ such that $K \xrightarrow{\sigma} K'$ and $K'\sigma = C$.
- (2) For all auxiliary continuations Q , if $Q \rightsquigarrow C$, there exist an auxiliary continuation Q' and a finite map σ such that $Q \xrightarrow{\sigma} Q'$ and $Q'\sigma = C$.

Furthermore, the σ in both statements above can be chosen so that its domain is fresh with respect to any given finite set of indices.

Proof. Let C be a contractum of the continuation we wish to reduce. This contractum will not, in general, satisfy the side condition that holes must be linear; however we can show that, for any context with duplicated holes, there exists a structurally equal context with linear holes.

Operationally, if C contains n holes, we generate n different fresh indices in \mathcal{P} , and replace the index of each hole in C with a different fresh index to obtain a new context C' : this induces a finite map $\sigma : \text{supp}(C') \rightarrow \text{supp}(C)$ such that $C'\sigma = C$. By structural induction on the derivation of the reduction and by case analysis on the structure of K (or on the structure of Q) we show that C' must also satisfy the grammar in Definition 3.5 (resp. Definition 3.6); furthermore, C' satisfies the linearity condition by construction, which proves it is a continuation K' (resp. an auxiliary continuation Q'). \square

Secondly, given a renaming reduction $C \xrightarrow{\sigma} C'$, we want to be able to express the corresponding reduction on $C\eta$: due to the renaming σ , it is not enough to change C to C' , but we also need to construct some η' containing precisely those mappings $[q \mapsto M]$ such that, if $\sigma(q) = p$, then $p \in \text{dom}(\eta)$ and $\eta(p) = M$. This construction is expressed by means of the following operation.

Definition 3.19. For all pure hole instantiations η and renamings σ , we define η^σ as the hole instantiation such that:

- if $\sigma(p) \in \text{dom}(\eta)$ then $\eta^\sigma(p) = \eta(\sigma(p))$;
- in all other cases, $\eta^\sigma(p) = \eta(p)$.

The results above allow us to express what happens when a reduction duplicates the holes in a continuation which is then combined with a hole instantiation.

Lemma 3.20. For all contexts C and hole instantiations η , if $C \rightsquigarrow C'$, then $C\eta \rightsquigarrow C'\eta$.

Proof. Routine induction on the derivation of $C \rightsquigarrow C'$. \square

Lemma 3.21. For all contexts C , finite maps σ , and hole instantiations η such that, for all $p \in \text{dom}(\eta)$, $\text{supp}(\eta(p)) \cap \text{dom}(\sigma) = \emptyset$, we have $C\sigma\eta = C\eta^\sigma\sigma$.

Proof. By structural induction on C . The interesting case is when $C = [p]$. If $\sigma(p) \in \text{dom}(\eta)$, we have $[p]\sigma\eta = [\sigma(p)]\eta = \eta(\sigma(p)) = \eta(\sigma(p))\sigma = [p]\eta^\sigma\sigma$; otherwise, $[p]\sigma\eta = [p] = [p]\eta^\sigma\sigma$. \square

Lemma 3.22. *For all contexts C , renamings σ , and hole instantiations η such that, for all $p \in \text{dom}(\eta)$, $\text{supp}(\eta(p)) \cap \text{dom}(\sigma) = \emptyset$, if $C \overset{\sigma}{\rightsquigarrow} C'$, then $C\eta \overset{\sigma}{\rightsquigarrow} C'\eta^\sigma$.*

Proof. By definition of $\overset{\sigma}{\rightsquigarrow}$, we have $C \rightsquigarrow C'\sigma$; then, by Lemma 3.20, we obtain $C\eta \rightsquigarrow C'\sigma\eta$; by Lemma 3.21, we know $C'\sigma\eta = C'\eta^\sigma\sigma$; then the thesis $C\eta \overset{\sigma}{\rightsquigarrow} C'\eta^\sigma$ follows immediately by the definition of $\overset{\sigma}{\rightsquigarrow}$. \square

Remark 3.23. In [Coo09a], Cooper attempts to prove strong normalization for NRC_λ using a similar, but weaker result:

If $K \rightsquigarrow C$, then for all terms M there exists K'_M such that $C[M] = K'_M[M]$ and $K[M] \rightsquigarrow K'_M[M]$.

Since he does not have branching continuations and renaming reductions, whenever a hole is duplicated, e.g.

$$K = \bigcup \{N_1 \cup N_2 \mid x \leftarrow \square\} \rightsquigarrow \bigcup \{N_1 \mid x \leftarrow \square\} \cup \bigcup \{N_2 \mid x \leftarrow \square\} = C$$

he resorts to obtaining a continuation from C simply by filling one of the holes with the instantiation M :

$$K'_M = \bigcup \{N_1 \mid x \leftarrow M\} \cup \bigcup \{N_2 \mid x \leftarrow \square\}$$

Hence, $K'_M[M] = C[M]$. Unfortunately, subsequent proofs rely on the fact that $\nu(K)$ must decrease under reduction: since we have no control over $\nu(M)$, which could potentially be much greater than $\nu(K)$, it may be that $\nu(K'_M) \geq \nu(K)$.

In our setting, by combining Lemmas 3.18 and 3.22, we can find a K' which is a proper contractum of K . By Lemma 3.11, we get $\nu(K') < \nu(K)$, as required by subsequent proofs.

More generally, the following lemma will help us in performing case analysis on the reduction of an applied continuation.

Lemma 3.24 (classification of reductions in applied continuations). *Suppose $Q\eta \rightsquigarrow N$, where η is permutable, and $\text{dom}(\eta) \subseteq \text{supp}(Q)$; then one of the following holds:*

- (1) *there exist an auxiliary continuation Q' and a finite map σ such that $N = Q'\eta^\sigma$, where η^σ is permutable, and $Q \overset{\sigma}{\rightsquigarrow} Q'$: in this case, we say the reduction is within Q ;*
- (2) *there exist auxiliary continuations Q_1, Q_2 , an index $q \in \text{supp}(Q_1)$, a variable x , and a term L such that $Q = (Q_1 \textcircled{+} \bigcup \{x \leftarrow \{\bar{L}\}\})[q \mapsto Q_2]$, and $N = Q_1[q \mapsto Q_2 \textcircled{+} \bar{L}/x]\eta^*$, where we define $\eta^*(p) = \eta(p) \textcircled{+} \bar{L}/x$ for all $p \in \text{supp}(Q_2)$, otherwise $\eta^*(p) = \eta(p)$: this is a reduction within Q too;*
- (3) *there exists a permutable η' such that $N = Q\eta'$ and $\eta \rightsquigarrow \eta'$: in this case we say the reduction is within η ;*
- (4) *there exist an auxiliary continuation Q_0 , an index p such that $p \in \text{supp}(Q_0)$ and $p \in \text{dom}(\eta)$, an auxiliary frame f and a term M such that $N = Q_0[p \mapsto M]\eta_{-p}$, $Q = Q_0 \textcircled{+} F$, and $F^p[p \mapsto \eta(p)] \rightsquigarrow M$: in this case we say the reduction is at the interface.*

Furthermore, if Q is a regular continuation K , then the Q' in case 1 can be chosen to be a regular continuation K' , and case 2 cannot happen.

Proof. By induction on Q with a case analysis on the reduction rule applied. In case 1, to ensure η^σ is permutable, we use Lemma 3.18 to generate a σ such that the indices of its domain are fresh with respect to the codomain of η . \square

The following result, like many other in the rest of this section, proceeds by well-founded induction; we will use the following notation to represent well-founded relations:

- $<$ stands for the standard less-than relation on \mathbb{N} , which is well-founded;
- \leq is the lexicographic extension of $<$ to k -tuples in \mathbb{N}^k (for a given k), also well-founded;
- \prec will be used to provide a decreasing metric that depends on the specific proof: such metrics are defined as subsets of \leq and are thus well-founded.

Lemma 3.25. *Let Q be an auxiliary continuation, and let η, θ be context instantiations s.t. their union is permutable. If $Q\eta \in \mathcal{SN}$ and $Q\theta \in \mathcal{SN}$, then $Q\eta\theta \in \mathcal{SN}$.*

Proof. We assume that $\text{dom}(\eta) \cup \text{dom}(\theta) \subseteq \text{supp}(Q)$ (otherwise, we can find strictly smaller permutable η', θ' such that $Q\eta\theta = Q\eta'\theta'$, and their domains are subsets of $\text{supp}(Q)$). We show $Q\eta \in \mathcal{SN}$ and $Q\theta \in \mathcal{SN}$ imply $Q \in \mathcal{SN}$, $\eta \in \mathcal{SN}$ and $\theta \in \mathcal{SN}$; thus we can then prove the theorem by well-founded induction on (Q, η, θ) using the following metric:

$$(Q_1, \eta_1, \theta_1) \prec (Q_2, \eta_2, \theta_2) \iff (\nu(Q_1), \|Q_1\|, \nu(\eta_1) + \nu(\theta_1)) \leq (\nu(Q_2), \|Q_2\|, \nu(\eta_2) + \nu(\theta_2))$$

We show that all of the possible contracta of $Q\eta\theta$ are s.n. by case analysis on the contraction. The important cases are the following:

- $Q'\eta^\sigma\theta^\sigma$, where $Q \xrightarrow{\sigma} Q'$: it is easy to see that $\nu(\eta^\sigma)$ and $\nu(\theta^\sigma)$ are defined because $\nu(\eta)$ and $\nu(\theta)$ are; then the thesis follows from the induction hypothesis, knowing that $\nu(Q') < \nu(Q)$ (Lemma 3.11).
- $Q_0[p \mapsto N]\eta_0\theta$ where $Q = Q_0 \oplus F$, $\eta = [p \mapsto M]\eta_0$, and $F^p[p \mapsto M] \rightsquigarrow N$ by means of a reduction at the interface. By Lemma 3.12 we know $\nu(Q_0) \leq \nu(Q)$; we can easily prove $\|Q_0\| < \|Q\|$. We take $\eta' = [p \mapsto N]\eta_0$: since $Q\eta$ reduces to $Q_0\eta'$ and both terms are strongly normalizing, we have that $\nu(\eta')$ is defined. Then we observe $(Q_0, \eta', \theta) \prec (Q, \eta, \theta)$ and obtain the thesis by induction hypothesis. A symmetric case with $p \in \text{dom}(\theta)$ is proved similarly. \square

Corollary 3.26. *$Q[p \mapsto M]^\sigma \in \mathcal{SN}$ iff for all q s.t. $\sigma(q) = p$, we have $Q[q \mapsto M] \in \mathcal{SN}$.*

Proof. By the definition of $[p \mapsto M]^\sigma$, using Lemma 3.25 to decompose the resulting context instantiation. \square

The following property tells us that instantiating a continuation never shortens the maximal reduction chain.

Lemma 3.27. *If $Q\eta \in \mathcal{SN}$, then $Q \in \mathcal{SN}$ and $\nu(Q) \leq \nu(Q\eta)$.*

Proof. We proceed by well-founded induction on (Q, η) using the metric:

$$(Q_1, \eta_1) \prec (Q_2, \eta_2) \iff \exists \sigma : Q\eta_1 \xrightarrow{\sigma} Q'\eta_2$$

For all contractions $Q \xrightarrow{\sigma} Q'$, by Lemma 3.22 we know $Q\eta \xrightarrow{\sigma} Q'\eta^\sigma$: then we can apply the IH with (Q', η^σ) to prove Q' : thus we conclude $Q \in \mathcal{SN}$.

To prove $\nu(Q) \leq \nu(Q\eta)$, it is sufficient to see that for each reduction step in Q we have a corresponding reduction step in $Q\eta$: thus the reduction chains starting in $Q\eta$ must be at least as long as those in Q . \square

3.3. Candidates of reducibility. We here define the notion of *candidates of reducibility*: sets of strongly normalizing terms enjoying certain closure properties that can be used to overapproximate the sets of terms of a certain type. Our version of candidates for NRC_λ is a straightforward adaptation of the standard definition given by Girard and like that one is based on a notion of *neutral terms*, i.e. those terms that, when placed in an arbitrary context, do not create additional redexes. The set of neutral terms is denoted by \mathcal{NT} . Let us introduce the following notation for Girard's CRx properties of sets [GLT89]:

- $\text{CR1}(\mathcal{C}) \triangleq \mathcal{C} \subseteq \mathcal{SN}$
- $\text{CR2}(\mathcal{C}) \triangleq \forall M \in \mathcal{C}, \forall M'. M \rightsquigarrow M' \implies M' \in \mathcal{C}$
- $\text{CR3}(\mathcal{C}) \triangleq \forall M \in \mathcal{NT}. (\forall M'. M \rightsquigarrow M' \implies M' \in \mathcal{C}) \implies M \in \mathcal{C}$

The set \mathcal{CR} of the candidates of reducibility is then defined as the collection of those sets of terms which satisfy all the CRx properties. Some standard results include the non-emptiness of candidates (in particular, all free variables are in every candidate) and that $\mathcal{SN} \in \mathcal{CR}$.

3.4. Reducibility sets. In this section we introduce *reducibility sets*, which are sets of terms that we will use to provide an interpretation of the types of NRC_λ ; we will then prove that reducibility sets are candidates of reducibility, hence they only contain strongly normalizing terms. The following notation will be useful as a shorthand for certain operations on sets of terms that are used to define reducibility sets:

- $\mathcal{C} \rightarrow \mathcal{D} \triangleq \{M : \forall N \in \mathcal{C}, (M N) \in \mathcal{D}\}$
- $\langle \ell_k : \mathcal{C}_k \rangle \triangleq \{M : \forall i = 1, \dots, k, M.\ell_i \in \mathcal{C}_i\}$
- $\mathcal{C}_p^\top \triangleq \{K : \forall M \in \mathcal{C}. K[p \mapsto \{M\}] \in \mathcal{SN}\}$
- $\mathcal{C}^{\top\top} \triangleq \{M : \forall p, \forall K \in \mathcal{C}_p^\top, K[p \mapsto M] \in \mathcal{SN}\}$

The sets \mathcal{C}_p^\top and $\mathcal{C}^{\top\top}$ are called the \top -lifting and $\top\top$ -lifting of \mathcal{C} . These definitions refine the ones used in the literature by using indices: \top -lifting is defined with respect to a given index p , while the definition of $\top\top$ -lifting uses any index (in the standard definitions, continuations only contain a single hole, and no indices are mentioned).

Definition 3.28 (reducibility). For all types T , the set Red_T of reducible terms of type T is defined by recursion on T by means of the rules:

$$\begin{array}{ll} \text{Red}_A \triangleq \mathcal{SN} & \text{Red}_{S \rightarrow T} \triangleq \text{Red}_S \rightarrow \text{Red}_T \\ \text{Red}_{\langle \ell_k : T_k \rangle} \triangleq \langle \ell_k : \text{Red}_{T_k} \rangle & \text{Red}_{\{T\}} \triangleq \text{Red}_T^{\top\top} \end{array}$$

Let us use metavariables $\mathcal{S}, \mathcal{S}', \dots$ to denote finite sets of indices: we provide a refined notion of \top -lifting $\mathcal{C}_\mathcal{S}^\top$ depending on a set of indices rather than a single index, defined by pointwise intersection. This notation is useful to track a \top -lifted candidate under renaming reduction.

Definition 3.29. $\mathcal{C}_\mathcal{S}^\top \triangleq \bigcap_{p \in \mathcal{S}} \mathcal{C}_p^\top$.

Definition 3.30. Let \mathcal{C} and \mathcal{S} sets of terms and indices respectively, and σ a finite renaming: then we define $(\mathcal{C}_\mathcal{S}^\top)^\sigma := \mathcal{C}_{\sigma^{-1}(\mathcal{S})}^\top$, where $\sigma^{-1}(\mathcal{S}) = \{q : \sigma(q) \in \mathcal{S}\}$

We now proceed with the proof that all the sets Red_T are candidates of reducibility: we will only focus on collections since for the other types the result is standard. The proofs of CR1 and CR2 do not differ much from the standard $\top\top$ -lifting technique.

Lemma 3.31. *Suppose $\text{CR1}(\mathcal{C})$: then for all indices p, q , $[p] \in (q \mapsto \mathcal{C})^\top$.*

Proof. To prove the lemma, it is sufficient to show that for all $M \in \mathcal{C}$ we have $[p][q \mapsto \{M\}] \in \mathcal{SN}$. This term is equal to either $\{M\}$ (if $p = q$) or to $[p]$ (otherwise); both terms are s.n. (in the case of $\{M\}$, this is because CR1 holds for \mathcal{C} , thus $M \in \mathcal{SN}$). \square

Lemma 3.32 (CR1 for continuations). *For all p and all non-empty \mathcal{C} , $\mathcal{C}_p^\top \subseteq \mathcal{SN}$.*

Proof. We assume $K \in \mathcal{C}_p^\top$ and $M \in \mathcal{C}$: by definition, we know that $K[p \mapsto \{M\}] \in \mathcal{SN}$; then we have $K \in \mathcal{SN}$ by Lemma 3.9. \square

Lemma 3.33 (CR1 for collections). *If $\text{CR1}(\mathcal{C})$, then $\text{CR1}(\mathcal{C}^{\top\top})$.*

Proof. We need to prove that if $M \in \mathcal{C}^{\top\top}$, then $M \in \mathcal{SN}$. By the definition of $\mathcal{C}^{\top\top}$, we know that for all p , $K[p \mapsto M] \in \mathcal{SN}$ whenever $K \in \mathcal{C}_p^\top$. Now assume any p , and by Lemma 3.31 choose $K = [p]$: then $K[p \mapsto M] = M \in \mathcal{SN}$, which proves the thesis. \square

Lemma 3.34 (CR2 for collections). *If $M \in \mathcal{C}^{\top\top}$ and $M \rightsquigarrow M'$, then $M' \in \mathcal{C}^{\top\top}$.*

Proof. Let p be an index, and take $K \in \mathcal{C}_p^\top$: we need to prove $K[p \mapsto M'] \in \mathcal{SN}$. By the definition of $M \in \mathcal{C}^{\top\top}$, we have $K[p \mapsto M] \in \mathcal{SN}$; if $p \notin \text{supp}(K)$, $K[p \mapsto M'] = K[p \mapsto M]$ and the thesis trivially holds; otherwise the instantiation is effective and we have $K[p \mapsto M] \rightsquigarrow K[p \mapsto M']$, and this last term, being a contractum of a strongly normalizing term, is strongly normalizing as well. This proves the thesis. \square

In order to prove CR2 for all types (and particularly for collections), we do not need to establish an analogous property on continuations; however such a property is still useful for subsequent results (particularly CR3). Its statement must, of course, consider that reduction may duplicate (or indeed delete) holes, and thus employs renaming reduction. We can show that whenever we need to prove a statement about n -ary permutable instantiations of n -ary continuations, we can simply consider each hole separately, as stated in the following lemma.

Lemma 3.35. *$K \in (\mathcal{C}_S^\top)^\sigma$ if, and only if, for all $q \in \sigma^{-1}(\mathcal{S})$, we have $K \in \mathcal{C}_q^\top$. In particular, $K \in (\mathcal{C}_p^\top)^\sigma$ if, and only if, for all q s.t. $\sigma(q) = p$, we have $K \in \mathcal{C}_q^\top$.*

Proof. Trivial by definition of Θ^σ and $(\cdot)^\top$, using Corollary 3.26. \square

Lemma 3.36 (CR2 for continuations). *If $K \in \mathcal{C}_S^\top$ and $K \rightsquigarrow^\sigma K'$, then $K' \in (\mathcal{C}_S^\top)^\sigma$.*

Proof. By the definition of $(\cdot)^\top$ and $(\cdot)^\sigma$, it suffices to prove that $K'[q \mapsto \{M\}] \in \mathcal{SN}$ for all q such that $\sigma(q) \in \mathcal{S}$ and $M \in \mathcal{C}$. Then we know $K[\sigma(q) \mapsto \{M\}] \in \mathcal{SN}$, and consequently $K'[\sigma(q) \mapsto \{M\}]^\sigma \in \mathcal{SN}$ as well, since the latter is a contractum of the former; finally, by Corollary 3.26, $K'[q \mapsto \{M\}] \in \mathcal{SN}$, as we needed. \square

This is everything we need to prove CR3.

Lemma 3.37 (CR3 for collections). *Let $\mathcal{C} \in \mathcal{CR}$, and M a neutral term such that for all reductions $M \rightsquigarrow M'$ we have $M' \in \mathcal{C}^{\top\top}$. Then $M \in \mathcal{C}^{\top\top}$.*

Proof. By definition, we need to prove $K[p \mapsto M] \in \mathcal{SN}$ whenever $K \in \mathcal{C}_p^\top$ for some index p . By Lemma 3.32, knowing that \mathcal{C} , being a candidate, is non-empty, we have $K \in \mathcal{SN}$. We can thus proceed by well-founded induction on $\nu(K)$ to prove the strengthened statement: for all indices q , if $K \in (q : \mathcal{C})^\top$, then $K[q \mapsto M] \in \mathcal{SN}$. Equivalently, we prove that all the contracta of $K[q \mapsto M]$ are s.n. by cases on the possible contracta:

- $K'[q \mapsto M]^\sigma$ (where $K \overset{\sigma}{\rightsquigarrow} K'$): to prove this term is s.n., by Corollary 3.26, we need to show $K'[q' \mapsto M] \in \mathcal{SN}$ whenever $\sigma(q') = q$; by Lemmas 3.36 and 3.35, we know $K' \in \mathcal{C}_q^\top$, and naturally $\nu(K') < \nu(K)$ (Lemma 3.11), thus the thesis follows by the IH.
- $K[p \mapsto M']$ (where $M \rightsquigarrow M'$): this is s.n. because $M' \in \mathcal{C}^{\top\top}$ by hypothesis.
- Since M is neutral, there are no reductions at the interface. \square

Theorem 3.38. *For all types T , $\text{Red}_T \in \mathcal{CR}$.*

Proof. Standard by induction on T . For $T = \{T'\}$, we use Lemmas 3.33, 3.34, and 3.37. \square

4. STRONG NORMALIZATION

Having proved that the reducibility sets of all types are candidates of reducibility, in order to obtain strong normalization we only need to know that every well-typed term is in the reducibility set corresponding to its type: this proof is by structural induction on the derivation of the typing judgment. We will proceed by first proving lemmas that show the typing rules preserve reducibility, concluding at the end with the fundamental theorem. Once again, we will focus our attention on the results corresponding to collection types, as the rest are standard.

Reducibility of singletons is trivial by definition, while that of empty collections is proved in the same style as [Coo09a], with the obvious adaptations.

Lemma 4.1 (reducibility for singletons). *For all \mathcal{C} , if $M \in \mathcal{C}$, then $\{M\} \in \mathcal{C}^{\top\top}$.*

Proof. Trivial by definition of \top -lifting and $\top\top$ -lifting. \square

Lemma 4.2. *If $K \in \mathcal{SN}$ is a continuation, then for all indices p we have $K[p \mapsto \emptyset] \in \mathcal{SN}$.*

Corollary 4.3 (reducibility for \emptyset). *For all \mathcal{C} , $\emptyset \in \mathcal{C}^{\top\top}$.*

As for unions, we will prove a more general statement on auxiliary continuations.

Lemma 4.4.

For all auxiliary continuations Q, O_1, O_2 with pairwise disjoint supports, if $Q[p \mapsto O_1] \in \mathcal{SN}$ and $Q[p \mapsto O_2] \in \mathcal{SN}$, then $Q[p \mapsto O_1 \cup O_2] \in \mathcal{SN}$.

The proof of the lemma above follows the same style as [Coo09a]; however since our definition of auxiliary continuations is more general, the theorem statement mentions O_1, O_2 rather than pure terms: the hypothesis on the supports of the continuations being disjoint is required by this generalization.

Corollary 4.5 (reducibility for unions). *If $M \in \mathcal{C}^{\top\top}$ and $N \in \mathcal{C}^{\top\top}$, then $M \cup N \in \mathcal{C}^{\top\top}$.*

Like in proofs based on standard $\top\top$ -lifting, the most challenging cases are those dealing with commuting conversions – in our case, comprehensions and conditionals.

Lemma 4.6. *Let K, \bar{L}, \bar{N} be such that $K[p \mapsto \bar{N}[\bar{L}/x]] \in \mathcal{SN}$ and $\bar{L} \in \mathcal{SN}$. Then $K[p \mapsto \bigcup\{\bar{N}|x \leftarrow \{\bar{L}\}\}] \in \mathcal{SN}$.*

Proof. In this proof, we assume the names of bound variables are chosen so as to avoid duplicates, and are distinct from the free variables. We proceed by well-founded induction on $(K, p, \overline{N}, \overline{L})$ using the following metric:

$$\begin{aligned} (K_1, p_1, \overline{N}_1, \overline{L}_1) &\prec (K_2, p_2, \overline{N}_2, \overline{L}_2) \\ \iff &(\nu(K_1[p_1 \mapsto \overline{N}_1[\overline{L}_1/x]]) + \nu(\overline{L}_1), \|K_1\|_{p_1}, \text{size}(\overline{N}_1)) \\ &\prec (\nu(K_2[p_2 \mapsto \overline{N}_2[\overline{L}_2/x]]) + \nu(\overline{L}_2), \|K_2\|_{p_2}, \text{size}(\overline{N}_2)) \end{aligned}$$

Now we show that every contractum must be a strongly normalizing:

- $K[p \mapsto \overline{N}[\overline{L}/x]]$: this term is s.n. by hypothesis.
- $K'[p \mapsto \bigcup\{N|x \leftarrow \{\overline{L}\}\}]^\sigma$, where $K \stackrel{\sigma}{\rightsquigarrow} K'$. Lemma 3.11 allows us to prove $\nu(K'[p \mapsto \overline{N}[\overline{L}/x]]^\sigma) < \nu(K[p \mapsto \overline{N}[\overline{L}/x]])$ (since the former is a contractum of the latter), which implies $\nu(K'[q \mapsto \overline{N}[\overline{L}/x]]) \leq \nu(K'[p \mapsto \overline{N}[\overline{L}/x]]^\sigma) < \nu(K[p \mapsto \overline{N}[\overline{L}/x]])$ for all q s.t. $\sigma(q) = p$ by means of Lemma 3.27 (because $[q \mapsto \overline{N}[\overline{L}/x]]$ is a subapplication of $[p \mapsto \overline{N}[\overline{L}/x]]^\sigma$); then we can apply the IH to obtain, for all q s.t. $\sigma(q) = p$, $K'[q \mapsto \bigcup\{\overline{N}|x \leftarrow \{\overline{L}\}\}] \in \mathcal{SN}$; by Corollary 3.26, this implies the thesis.
- $K[p \mapsto \emptyset]$ (when $N = \emptyset$): this is equal to $K[p \mapsto \emptyset[\overline{L}/x]]$, which is s.n. by hypothesis.
- $K[p \mapsto \bigcup\{\overline{N}_1|x \leftarrow \{\overline{L}\}\} \cup \bigcup\{\overline{N}_2|x \leftarrow \{\overline{L}\}\}]$ (when $\overline{N} = \overline{N}_1 \cup \overline{N}_2$); by IH (since $\text{size}(\overline{N}_i) < \text{size}(\overline{N}_1 \cup \overline{N}_2)$, and all other metrics do not increase) we prove $K[p \mapsto \bigcup\{\overline{N}_i|x \leftarrow \{\overline{L}\}\}] \in \mathcal{SN}$ (for $i = 1, 2$), and consequently obtain the thesis by Lemma 4.4.
- $K_0[p \mapsto \bigcup\{\bigcup\{\overline{M}|y \leftarrow \overline{N}\}|x \leftarrow \{\overline{L}\}\}]$, where $K = K_0 \oplus \bigcup\{\overline{M}|y\}$; since we know, by the hypothesis on the choice of bound variables, that $x \notin \text{FV}(\overline{M})$, we note that $K_0[p \mapsto \bigcup\{\overline{M}|y \leftarrow \overline{N}\}[\overline{L}/x]] = K[p \mapsto \overline{N}[\overline{L}/x]]$; furthermore, we know $\|K_0\|_p < \|K\|_p$; then we can apply the IH to obtain the thesis.
- $K_0[p \mapsto \bigcup\{\text{where } \overline{B} \text{ do } \overline{N}|x \leftarrow \{\overline{L}\}\}]$ (when $K = K_0 \oplus \text{where } \overline{B}$): since we know, from the hypothesis on the choice of bound variables, that $x \notin \text{FV}(\overline{B})$, we note that $K_0[p \mapsto (\text{where } \overline{B} \text{ do } \overline{N})[\overline{L}/x]] = K[p \mapsto \overline{N}[\overline{L}/x]]$; furthermore, we know $\|K_0\|_p < \|K\|_p$; then we can apply the IH to obtain the thesis.
- reductions within N or L follow from the IH by reducing the induction metric. \square

Lemma 4.7 (reducibility for comprehensions). *Assume $\text{CR1}(\mathcal{C})$, $\text{CR1}(\mathcal{D})$, $\overline{M} \in \mathcal{C}^{\top\top}$ and for all $\overline{L} \in \mathcal{C}$, $\overline{N}[\overline{L}/x] \in \mathcal{D}^{\top\top}$. Then $\bigcup\{\overline{N}|x \leftarrow \overline{M}\} \in \mathcal{D}^{\top\top}$.*

Proof. We assume $p, K \in (p : \mathcal{D})^\top$ and prove $K[p \mapsto \bigcup\{\overline{N}|x \leftarrow \overline{M}\}] \in \mathcal{SN}$. We start by showing that $K' = K \oplus \bigcup\{\overline{N}|x\} \in (p : \mathcal{C})^\top$, or equivalently that for all $\overline{L} \in \mathcal{C}$, $K'[p \mapsto \{\overline{L}\}] = K[p \mapsto \bigcup\{\overline{N}|x \leftarrow \{\overline{L}\}\}] \in \mathcal{SN}$: since $\text{CR1}(\mathcal{C})$, we know $\overline{L} \in \mathcal{SN}$, and since $\overline{N}[\overline{L}/x] \in \mathcal{D}^{\top\top}$, $K[p \mapsto \overline{N}[\overline{L}/x]] \in \mathcal{SN}$; then we can apply Lemma 4.6 to obtain $K'[p \mapsto \{\overline{L}\}] \in \mathcal{SN}$ and consequently $K' \in \mathcal{C}^\top$. But then, since $\overline{M} \in \mathcal{C}^{\top\top}$, we have $K'[p \mapsto \overline{M}] = K[p \mapsto \bigcup\{\overline{N}|x \leftarrow \overline{M}\}] \in \mathcal{SN}$, which is what we needed to prove. \square

Reducibility for conditionals is proved in a similar manner. However, to consider all the conversions commuting with **where**, we need to use the more general auxiliary continuations. A minor complication with the merging of nested **where** is handled by a separate lemma.

Lemma 4.8. *Suppose $Q[p \mapsto \text{where } B \text{ do } M] \in \mathcal{SN}$. Then for all $B' \in \mathcal{SN}$ such that $\text{BV}(Q)$ and $\text{FV}(B')$ are disjoint, $Q[p \mapsto \text{where } B \wedge B' \text{ do } M] \in \mathcal{SN}$.*

Lemma 4.9. *Let Q, B, O such that $Q[p \mapsto O] \in \mathcal{SN}$, $B \in \mathcal{SN}$, $\text{BV}(Q) \cap \text{FV}(B) = \emptyset$ and $\text{supp}(Q) \cap \text{supp}(O) = \emptyset$. Then $Q[p \mapsto \text{where } B \text{ do } O] \in \mathcal{SN}$.*

Proof. In this proof, we assume the names of bound variables are chosen so as to avoid duplicates, and distinct from the free variables. We proceed by well-founded induction on (Q, B, O, p) using the following metric:

$$\begin{aligned} (Q_1, B_1, O_1, p_1) \prec (Q_2, B_2, O_2, p_2) &\iff \\ (\nu(Q_1[p_1 \mapsto O_1]), |Q_1|_{p_1}, \text{size}(O_1), \nu(B_1)) & \\ \prec (\nu(Q_2[p_2 \mapsto O_2]), |Q_2|_{p_2}, \text{size}(O_2), \nu(B_2)) & \end{aligned}$$

We will consider all possible contracta and show that each of them must be a strongly normalizing term; we will apply the induction hypothesis to new auxiliary continuations obtained by placing pieces of O into Q or vice-versa: the hypothesis on the supports of Q and O being disjoint is used to make sure that the new continuations do not contain duplicate holes and are thus well-formed. By cases on the possible contracta:

- $Q_1[q \mapsto Q_2 [\overline{L}/x]][p \mapsto (\text{where } B \text{ do } O) [\overline{L}/x]]$, where $Q = (Q_1 \odot_q \bigcup \{x \leftarrow \{\overline{L}\}\})[q \mapsto Q_2]$, $q \in \text{supp}(Q_1)$, and $p \in \text{supp}(Q_2)$; by the freshness condition we know $x \notin \text{FV}(B)$, thus $(\text{where } B \text{ do } O) [\overline{L}/x] = \text{where } B \text{ do } (O [\overline{L}/x])$; we take $Q' = Q_1[q \mapsto Q_2 [\overline{L}/x]]$ and $O' = O [\overline{L}/x]$, and note that $\nu(Q'[p \mapsto O']) < \nu(Q[p \mapsto O])$, because the former term is a contractum of the latter: then we can apply the IH to prove $Q'[p \mapsto \text{where } B \text{ do } O'] \in \mathcal{SN}$, as needed.
- $Q'[p \mapsto \text{where } B \text{ do } O]^\sigma$, where $Q \xrightarrow{\sigma} Q'$. We know $\nu(Q'[p \mapsto O]^\sigma) < \nu(Q[p \mapsto O])$ by Lemma 3.11 since the latter is a contractum of the former. By Corollary 3.26, for all q s.t. $\sigma(q) = p$ we have $\nu(Q'[q \mapsto O]) \leq \nu(Q'[p \mapsto O]^\sigma)$; we can thus apply the IH to obtain $Q[q \mapsto \text{where } B \text{ do } O] \in \mathcal{SN}$ whenever $\sigma(q) = p$. By Corollary 3.26, this implies the thesis.
- $Q_1[p \mapsto \text{where } B \text{ do } \bigcup \{Q_2|x \leftarrow O\}]$, where $Q = Q_1 \odot_p \bigcup \{Q_2|x\}$; we take $O' = \bigcup \{Q_2|x \leftarrow O\}$, and we note that $Q[p \mapsto O] = Q_1[p \mapsto O']$ and $|Q_1|_p < |Q|_p$; we can thus apply the IH to prove $Q_1[p \mapsto \text{where } B \text{ do } O'] \in \mathcal{SN}$, as needed.
- $Q_0[p \mapsto \text{where } (B_0 \wedge B) \text{ do } O]$, where $Q = Q_0 \odot_p \text{where } B_0$; we know by hypothesis that $Q_0[p \mapsto \text{where } B_0 \text{ do } O] \in \mathcal{SN}$ and $B \in \mathcal{SN}$; then the thesis follows by Lemma 4.8.
- $Q[p \mapsto \emptyset]$, where $O = \emptyset$: this term is strongly normalizing by hypothesis.
- $Q[p \mapsto (\text{where } B \text{ do } O_1) \cup (\text{where } B \text{ do } O_2)]$, where $O = O_1 \cup O_2$; for $i = 1, 2$, we prove $Q[p \mapsto O_i] \in \mathcal{SN}$ and $\nu(Q[p \mapsto O_i]) \leq \nu(Q[p \mapsto O])$ by Lemma 4.4, and we also note $\text{size}(O_i) < \text{size}(O)$; then we can apply the IH to prove $Q[p \mapsto \text{where } B \text{ do } O_i] \in \mathcal{SN}$, which implies the thesis by Lemma 4.4.
- $Q[p \mapsto \bigcup \{\text{where } B \text{ do } O_1|x \leftarrow O_2\}]$, where $O = \bigcup \{O_1|x \leftarrow O_2\}$; we take $Q' = Q \odot_p \bigcup \{x \leftarrow O_2\}$ and we have that $Q'[p \mapsto \text{where } B \text{ do } O_1]$ is equal to $Q[p \mapsto \bigcup \{\text{where } B \text{ do } O_1|x \leftarrow O_2\}]$; we thus note $\nu(Q'[p \mapsto O_1]) = \nu(Q[p \mapsto O])$, $|Q'|_p = |Q|_p$, and $\text{size}(O_1) < \text{size}(O)$, thus we can apply the IH to prove $Q'[p \mapsto \text{where } B \text{ do } O_1] \in \mathcal{SN}$, as needed.
- $Q[p \mapsto \text{where } (B \wedge B_0) \text{ do } O_0]$, where $O = \text{where } B_0 \text{ do } O_0$; we know by hypothesis that $Q[p \mapsto \text{where } B_0 \text{ do } O_0] \in \mathcal{SN}$ and $B \in \mathcal{SN}$; then the thesis follows by Lemma 4.8.
- Reductions within B or O make the induction metric smaller, thus follow immediately from the IH. \square

Corollary 4.10 (reducibility for conditionals).

If $\overline{B} \in \mathcal{SN}$ and $\overline{N} \in \text{Red}_{\{T\}}$, then $\text{where } \overline{B} \text{ do } \overline{N} \in \text{Red}_{\{T\}}$.

Finally, reducibility for the emptiness test is proved in the same style as [Coo09a].

Lemma 4.11. *For all M and T such that $\Gamma \vdash M : \{T\}$ and $M \in \text{Red}_T^{\top\top}$, we have $\text{empty}(M) \in \mathcal{SN}$.*

4.1. Main theorem. Before stating and proving the main theorem, we introduce some auxiliary notation.

Definition 4.12.

- (1) A substitution ρ satisfies Γ (notation: $\rho \models \Gamma$) iff, for all $x \in \text{dom}(\Gamma)$, $\rho(x) \in \text{Red}_{\Gamma(x)}$.
- (2) A substitution ρ satisfies M with type T (notation: $\rho \models M : T$) iff $M\rho \in \text{Red}_T$.

As usual, the main result is obtained as a corollary of a stronger theorem generalized to substitutions into open terms, by using the identity substitution id_Γ .

Lemma 4.13. *For all Γ , we have $\text{id}_\Gamma \models \Gamma$.*

Theorem 4.14. *If $\Gamma \vdash M : T$, then for all ρ such that $\rho \models \Gamma$, we have $\rho \models M : T$*

Proof. By induction on the derivation of $\Gamma \vdash M : T$. When M is a singleton, an empty collection, a union, a conditional, or an emptiness test, we use Lemmas 4.1 and 4.11, and Corollaries 4.3, 4.5, and 4.10. For comprehensions such that $\Gamma \vdash \bigcup\{M_1 | x \leftarrow M_2\} : \{T\}$, we know by IH that $\rho \models M_2 : \{S\}$ and for all $\rho' \models \Gamma, x : S$ we have $\rho' \models M_1 : \{T\}$: we prove that for all $L \in \text{Red}_S$, $\rho[L/x] \models \Gamma, x : S$, hence $\rho[L/x] \vdash M_1 : \{T\}$; then we obtain $\rho \models \bigcup\{M_1 | x \leftarrow M_2\} : \{T\}$ by Lemma 4.7. Non-collection cases are standard. \square

Corollary 4.15. *If $\Gamma \vdash M : T$, then $M \in \mathcal{SN}$.*

5. HETEROGENEOUS COLLECTIONS

In a short paper [RC19], we introduced a generalization of NRC called $NRC(\text{Set}, \text{Bag})$, which contains both set-valued and bag-valued collections (with distinct types denoted by $\{T\}$ and $\wr T$), along with mappings from bags to sets (deduplication δ) and from sets to bags (promotion ι). We conjectured that this language also satisfies a normalization property. Here, we prove this claim, even extending $NRC(\text{Set}, \text{Bag})$ to a richer language $NRC_\lambda(\text{Set}, \text{Bag})$ with higher-order (nonrecursive) functions. Its syntax is a straightforward extension of NRC_λ :

$$\begin{array}{ll} \text{types} & S, T ::= \dots \mid \wr T \\ \text{terms} & L, M, N ::= \dots \mid \mathcal{U} \mid \wr M \mid M \uplus N \mid \wr M | x \leftarrow N \\ & \quad \mid \text{where}_{\text{bag}} M \text{ do } N \mid \delta M \mid \iota M \end{array}$$

We use $\wr T$ to denote the type of bags containing elements of type T ; similarly, the notations \mathcal{U} , $\wr M$, $M \uplus N$, $\wr M | x \leftarrow N$ denote empty and singleton bags, bag disjoint union and bag comprehension; the language also includes conditionals on bags. The notations ιM and δN stand, respectively, for the bag containing exactly one copy of each element of the set M , and for the set containing the elements of the bag N , forgetting about their multiplicity. We do not need to provide a primitive emptiness test for bags, since it can be defined anyway as $\text{empty}_{\text{bag}} M := \text{empty } \delta M$.

The type system for $NRC_\lambda(\text{Set}, \text{Bag})$ is obtained from the one for NRC_λ by adding the unsurprising rules of Figure 3: these largely replicate, at the bag level, the corresponding set-based rules; additionally, the rules for δ and ι describe how these operators turn bag-typed

$$\begin{array}{c}
\frac{}{\Gamma \vdash \bar{U} : \langle T \rangle} \quad \frac{\Gamma \vdash M : T}{\Gamma \vdash \langle M \rangle : \langle T \rangle} \quad \frac{\Gamma \vdash M : \langle T \rangle \quad \Gamma \vdash N : \langle T \rangle}{\Gamma \vdash M \uplus N : \langle T \rangle} \\
\frac{\Gamma, x : T \vdash M : \langle S \rangle \quad \Gamma \vdash N : \langle T \rangle}{\Gamma \vdash \langle M | x \leftarrow N \rangle : \langle S \rangle} \quad \frac{\Gamma \vdash M : \mathbf{B} \quad \Gamma \vdash N : \langle T \rangle}{\Gamma \vdash \text{where}_{\text{bag}} M \text{ do } N : \langle T \rangle} \\
\frac{\Gamma \vdash M : \langle T \rangle}{\Gamma \vdash \delta M : \{T\}} \quad \frac{\Gamma \vdash M : \{T\}}{\Gamma \vdash \iota M : \langle T \rangle}
\end{array}$$

Figure 3: Additional typing rules for $NRC_\lambda(\text{Set}, \text{Bag})$.

$$\begin{array}{l}
\langle \bar{U} | x \leftarrow M \rangle \rightsquigarrow \bar{U} \quad \langle M | x \leftarrow \bar{U} \rangle \rightsquigarrow \bar{U} \quad \langle M | x \leftarrow \langle N \rangle \rangle \rightsquigarrow M[N/x] \\

\delta \langle M | x \leftarrow N \rangle \rightsquigarrow \bigcup \{ \delta M | x \leftarrow \delta N \} \quad \delta(\text{where}_{\text{bag}} M \text{ do } N) \rightsquigarrow \text{where } M \text{ do } \delta N \\
\iota \emptyset \rightsquigarrow \bar{U} \quad \iota \{M\} \rightsquigarrow \langle M \rangle \quad \iota(\text{where } M \text{ do } N) \rightsquigarrow \text{where}_{\text{bag}} M \text{ do } \iota N
\end{array}$$

Figure 4: Additional rewrite rules for $NRC_\lambda(\text{Set}, \text{Bag})$.

terms into set-typed ones, and vice-versa. Similarly, the rewrite system for $NRC_\lambda(\text{Set}, \text{Bag})$ is also an extension of the one for NRC_λ , with additional reduction rules for the new operators involving bags that mimic the corresponding set-based operations; there are simplification rules involving δ that state that the deduplication of empty or singleton bags yields empty or singleton sets, and that deduplication commutes with bag union and comprehension, turning them into their set counterparts. The promotion of empty or singleton sets can be simplified away in a symmetric way; however, promotion does *not* commute with union and comprehension (this avoids contractions like $\iota(\{x\} \cup \{x\}) \not\rightsquigarrow \iota\{x\} \uplus \iota\{x\}$, which would be unsound in the intended model, where \cup is idempotent, but \uplus is not). These reduction rules are described in Figure 4.

An obvious characteristic of $NRC_\lambda(\text{Set}, \text{Bag})$, compared to NRC_λ , is the duplication of syntax caused by the presence of two separate types of collections. A direct proof of strong normalization of this calculus would require us to consider many more cases than we have seen in NRC_λ . A more efficient approach is to show that the strong normalization property of $NRC_\lambda(\text{Set}, \text{Bag})$ descends, as a corollary, from the strong normalization of a slightly tweaked version of NRC_λ , comprising a single type of collections, but also retaining the δ and ι operators of $NRC_\lambda(\text{Set}, \text{Bag})$. This is the formalism $NRC_{\lambda\delta\iota}$ described in the next subsection.

$$\begin{array}{c}
\frac{\Gamma \vdash M : \{T\}}{\Gamma \vdash \delta M : \{T\}} \quad \frac{\Gamma \vdash M : \{T\}}{\Gamma \vdash \iota M : \{T\}} \\
\\
\begin{array}{llll}
\delta \emptyset \rightsquigarrow \emptyset & \delta \{M\} \rightsquigarrow \{M\} & \delta(M \cup N) \rightsquigarrow \delta M \cup \delta N & \delta \iota M \rightsquigarrow M \\
\delta \bigcup \{M \mid x \leftarrow N\} \rightsquigarrow \bigcup \{\delta M \mid x \leftarrow \delta N\} & \delta(\text{where } M \text{ do } N) \rightsquigarrow \text{where } M \text{ do } \delta N & & \\
\iota \emptyset \rightsquigarrow \emptyset & \iota \{M\} \rightsquigarrow \{M\} & \iota(\text{where } M \text{ do } N) \rightsquigarrow \text{where } M \text{ do } \iota N &
\end{array}
\end{array}$$

Figure 5: Additional typing and rewrite rules for $NRC_{\lambda\delta\iota}$.

$$\begin{array}{l}
[A] = A \quad [S \rightarrow T] = [S] \rightarrow [T] \quad \left[\overrightarrow{\langle \ell : T \rangle} \right] = \overrightarrow{\langle \ell : [T] \rangle} \quad [\{T\}] = [\mathcal{L}T] = \{[T]\} \\
[x_1 : T_1, \dots, x_n : T_n] = x_1 : [T_1], \dots, x_n : [T_n] \\
\\
[x] = x \quad \left[c(\overrightarrow{M}) \right] = c(\overrightarrow{[M]}) \\
\left[\overrightarrow{\langle \ell = M \rangle} \right] = \overrightarrow{\langle \ell = [M] \rangle} \quad [M.\ell] = [M].\ell \\
[\lambda x.M] = \lambda x.[M] \quad [(M \ N)] = ([M] \ [N]) \\
[\emptyset] = [\mathcal{U}] = \emptyset \quad [\{M\}] = [\mathcal{L}M] = \{[M]\} \\
[M \cup N] = [M \uplus N] = [M] \cup [M] \quad [\text{empty } M] = \text{empty } [M] \\
\\
\left[\bigcup \{M \mid x \leftarrow N\} \right] = \left[\biguplus \{M \mid x \leftarrow N\} \right] = \bigcup \{[M] \mid x \leftarrow [N]\} \\
[\text{where } M \text{ do } N] = [\text{where}_{\text{bag}} M \text{ do } N] = \text{where } [M] \text{ do } [N]
\end{array}$$

Figure 6: Forgetful translation of $NRC_{\lambda}(Set, Bag)$ into $NRC_{\lambda\delta\iota}$.

5.1. The simplified language $NRC_{\lambda\delta\iota}$. The simplified language $NRC_{\lambda\delta\iota}$ is obtained from NRC_{λ} by adding the two operators δ , ι , and nothing else:

$$L, M, N ::= \dots \mid \delta M \mid \iota M$$

$NRC_{\lambda\delta\iota}$ does not add any type compared to NRC_{λ} : in particular, if M has type $\{T\}$, then δM and ιM have type $\{T\}$ as well. The rewrite system extends NRC_{λ} with straightforward adaptations of the $NRC_{\lambda}(Set, Bag)$ rules involving δ and ι . All of the additional typing and rewrite rules are shown in Figure 5.

$NRC_{\lambda}(Set, Bag)$ types and terms can be translated to $NRC_{\lambda\delta\iota}$ by means of a forgetful operation $[\cdot]$, described in Figure 6. A straightforward induction is sufficient to prove that this translation preserves typability and reduction.

Theorem 5.1. *If $\Gamma \vdash M : T$ in $NRC_{\lambda}(Set, Bag)$, then $[\Gamma] \vdash [M] : [T]$ in $NRC_{\lambda\delta\iota}$.*

Theorem 5.2. *For all terms M of $NRC_{\lambda}(Set, Bag)$, if $M \rightsquigarrow M'$, we have $[M] \rightsquigarrow [M']$ in $NRC_{\lambda\delta\iota}$. Consequently, if $[M] \in \mathcal{SN}$ in $NRC_{\lambda\delta\iota}$, then $M \in \mathcal{SN}$ in $NRC_{\lambda}(Set, Bag)$.*

Thanks to the two results above, strong normalization for $NRC_{\lambda}(Set, Bag)$ is an immediate consequence of strong normalization for $NRC_{\lambda\delta\iota}$.

5.2. Reducibility for $NRC_{\lambda\delta\iota}$. We are now going to present an extension of the strong normalization proof for NRC_λ , allowing us to derive the same result for $NRC_{\lambda\delta\iota}$ (and, consequently, for $NRC_\lambda(Set, Bag)$). Concretely, this extension involves adding some extra cases to some definitions and proofs; in a single case, we need to strengthen the statement of a lemma, whose proof remains otherwise close to its NRC_λ version.

For $NRC_{\lambda\delta\iota}$ continuations and frames, we will allow extra cases including δ and ι , as follows:

$$\begin{aligned} K, H &::= \dots \mid \delta K \mid \iota K \\ Q, O &::= \dots \mid \delta Q \mid \iota Q \\ F &::= \dots \mid \delta \mid \iota \end{aligned}$$

The new frames are lifted to continuations in the obvious way:

$$(\delta)^p = \delta[p] \quad (\iota)^p = \iota[p]$$

We also extend the measures $|Q|_p$ and $\|Q\|_p$ to account for the new cases.

Definition 5.3 (extends 3.8). The measures $|Q|_p$ and $\|Q\|_p$ of NRC_λ are extended to $NRC_{\lambda\delta\iota}$ by means of the following additional cases:

$$|\delta Q|_p = |\iota Q|_p = |Q|_p + 1 \quad \|\delta Q\|_p = \|\iota Q\|_p = \|Q\|_p + 1$$

Renaming reduction in $NRC_{\lambda\delta\iota}$ is defined in the same way as its NRC_λ counterpart.

Since the type sublanguage of $NRC_{\lambda\delta\iota}$ is the same as in NRC_λ , we can *superficially* reuse the definition of reducibility sets: however, it is intended that the terms and continuations appearing in these definitions are those of $NRC_{\lambda\delta\iota}$ rather than NRC_λ . Similarly, the proof that all reducibility sets are candidates uses $NRC_{\lambda\delta\iota}$ terms and continuations, but does not need to change structurally (in particular, in the proof of CR3, we do not need to consider any of the additional cases for an $NRC_{\lambda\delta\iota}$ continuation K , because K is applied to a neutral term, therefore there are no redexes at the interface regardless of the shape of K).

However, we do need to prove that the additional typing rules of $NRC_{\lambda\delta\iota}$ (i.e. the introduction rules for δ and ι) preserve reducibility. This is expressed by the following results:

Lemma 5.4. *For all indices p and candidates $\mathcal{C} \in \mathcal{CR}$, if $K \in \mathcal{C}_p^\top$, then $K \oplus_p \delta \in \mathcal{C}_p^\top$.*

Proof. By unfolding the definitions, we prove that for all p , if $K \in \mathcal{C}_p^\top$ and $M \in \mathcal{C}$, then $K[p \mapsto \delta\{M\}] \in \mathcal{SN}$. We proceed by well-founded induction on (K, M) using the following metric:

$$(K_1, M_1) \prec (K_2, M_2) \iff (\nu(K_1), \nu(M_1)) \triangleleft (\nu(K_2), \nu(M_2))$$

Equivalently, we prove that all the contracta of $K[p \mapsto \delta\{M\}]$ are s.n.:

- $K'[p \mapsto \delta\{M\}]^\sigma$ (where $K \stackrel{\sigma}{\rightsquigarrow} K'$): to prove this term is s.n., by Corollary 3.26 we need to show that $K'[p' \mapsto \delta\{M\}] \in \mathcal{SN}$ for all p' s.t. $\sigma(p') = p$; by Lemmas 3.36 and 3.35, we know $K' \in (\mathcal{C}_{p'}^\top)^\sigma$, and naturally $\nu(K') < \nu(K)$ (Lemma 3.11), so the thesis follows by the IH.
- $K[p \mapsto \delta\{M'\}]$ (where $M \rightsquigarrow M'$): by IH, with unchanged K , $M' \in \mathcal{C}$ (Lemma 3.36), and $\nu(M') < \nu(M)$ (Lemma 3.11).
- $K[p \mapsto \{M\}]$: this is trivial by hypothesis.

□

Corollary 5.5 (reducibility for δ). *For all $\mathcal{C} \in \mathcal{CR}$, if $M \in \mathcal{C}^{\top\top}$, then $\delta M \in \mathcal{C}^{\top\top}$.*

Proof. We need to prove that for all indices p , for all $K \in \mathcal{C}_p^\top$, we have $K[p \mapsto \delta M] \in \mathcal{SN}$. By Lemma 5.4, we prove $K \oplus \delta \in \mathcal{C}_p^\top$; since $M \in \mathcal{C}^{\top\top}$, we have $(K \oplus \delta)[p \mapsto M] \in \mathcal{SN}$, which is equivalent to the thesis. \square

Lemma 5.6. *For all indices p and candidates $\mathcal{C} \in \mathcal{CR}$, if $K \in \mathcal{C}_p^\top$, then $K \oplus \iota \in \mathcal{C}_p^\top$.*

Proof. By unfolding the definitions, we prove that for all p , if $K \in \mathcal{C}_p^\top$ and $M \in \mathcal{C}$, then $K[p \mapsto \iota\{M\}] \in \mathcal{SN}$. The proof follows the same steps as that of Lemma 5.4, but we have to consider an additional contractum for $K = K_0 \oplus \delta$:

$$K[p \mapsto \iota\{M\}] = K_0[p \mapsto \delta\iota\{M\}] \rightsquigarrow K_0[p \mapsto \{M\}]$$

Since $K \in \mathcal{C}_p^\top$ and $M \in \mathcal{C}$, we prove $K[p \mapsto \{M\}] = K_0[p \mapsto \delta\{M\}] \in \mathcal{SN}$. Thus, $K_0[p \mapsto \{M\}] \in \mathcal{SN}$ as well, being a contractum of that term. This proves the thesis. \square

Corollary 5.7 (reducibility for ι). *If $M \in \mathcal{C}^{\top\top}$, then $\iota M \in \mathcal{C}^{\top\top}$.*

Proof. We need to prove that for all indices p , for all $K \in \mathcal{C}_p^\top$, we have $K[p \mapsto \iota M] \in \mathcal{SN}$. By Lemma 5.6, we prove $K \oplus \iota \in \mathcal{C}_p^\top$; since $M \in \mathcal{C}^{\top\top}$, we have $(K \oplus \iota)[p \mapsto M] \in \mathcal{SN}$, which is equivalent to the thesis. \square

Finally, we need to reconsider the reducibility properties of unions, comprehensions, and conditionals (Lemmas 4.4, 4.6, and 4.9), to add the extra cases in the updated definition of continuations. In the case of comprehensions, we need to reformulate the statement in a slightly strengthened way to ensure that the induction hypothesis remains applicable.

Lemma 5.8 (extends 4.4).

For all auxiliary continuations Q, O_1, O_2 with pairwise disjoint supports, if $Q[p \mapsto O_1] \in \mathcal{SN}$ and $Q[p \mapsto O_2] \in \mathcal{SN}$, then $Q[p \mapsto O_1 \cup O_2] \in \mathcal{SN}$.

Proof. For $Q = Q_0 \oplus \delta$, $Q[p \mapsto O_1 \cup O_2]$ has an additional contractum $Q_0[p \mapsto \delta O_1 \cup \delta O_2]$. We prove that $\nu(Q_0) \leq \nu(Q)$ and $\|Q_0\|_p < \|Q\|_p$: then we can use the IH to prove the thesis. \square

We introduce the notation $\delta^n M$ as syntactic sugar for the δ operator applied n times to the term M (in particular: $\delta^0 M = M$). We use it to state and prove the following strengthened version of the reducibility lemma for comprehensions.

Lemma 5.9 (extends 4.6). *Let $K, \overline{L}, \overline{N}$ be such that $K[p \mapsto \overline{N} [\overline{L}/x]] \in \mathcal{SN}$ and $\overline{L} \in \mathcal{SN}$. Then for all n , $K[p \mapsto \bigcup\{\overline{N}|x \leftarrow \delta^n\{\overline{L}\}\}] \in \mathcal{SN}$.*

Proof. Due to the updated statement of this result, we need a stronger metric on $(K, p, \overline{N}, \overline{L}, n)$:

$$\begin{aligned} (K_1, p_1, \overline{N}_1, \overline{L}_1, n_1) &\prec (K_2, p_2, \overline{N}_2, \overline{L}_2, n_2) \\ \iff &(\nu(K_1[p_1 \mapsto \overline{N}_1 [\overline{L}_1/x]]) + \nu(\overline{L}_1), \|K_1\|_{p_1}, \text{size}(\overline{N}_1), n_1) \\ &\prec (\nu(K_2[p_2 \mapsto \overline{N}_2 [\overline{L}_2/x]]) + \nu(\overline{L}_2), \|K_2\|_{p_2}, \text{size}(\overline{N}_2), n_2) \end{aligned}$$

The cases considered in the proof of 4.6 can be mapped to this extended result in a straightforward manner (however, a reduction to $K[p \mapsto \overline{N} [\overline{L}/x]]$ is possible only if $n = 0$). We also need to consider the following two additional contracta:

- $K_0[p \mapsto \bigcup\{\delta\overline{N} \mid x \leftarrow \delta^{n+1}\{\overline{L}\}\}]$, where $K = K_0 \oplus \delta$: we prove $\nu(K_0[p \mapsto (\delta\overline{N}) [\overline{L}/x]]) = \nu(K[p \mapsto \overline{N} [\overline{L}/x]])$ and $\|K_0\|_p < \|K\|$: then the term is s.n. by IH.

- $K[p \mapsto \bigcup \{\overline{N} \mid x \leftarrow \delta^{n-1} \{\overline{L}\}\}]$, where $n > 0$: since $n - 1 < n$ and all of the other values involved in the metric are invariant, we can immediately apply the IH to obtain the thesis. \square

Lemma 5.10 (extends 4.9). *Let Q , \overline{B} , O such that $Q[p \mapsto O] \in \mathcal{SN}$, $\overline{B} \in \mathcal{SN}$, and $\text{supp}(Q) \cap \text{supp}(O) = \emptyset$. Then $Q[p \mapsto \text{where } \overline{B} \text{ do } O] \in \mathcal{SN}$.*

Proof. We need to consider the following additional contracta of $Q[p \mapsto \text{where } \overline{B} \text{ do } P]$:

- $Q_0[p \mapsto \text{where } \overline{B} \text{ do } \delta O]$, where $Q = Q_0 \oplus \delta$: we show that $\nu(Q_0[p \mapsto \delta O]) = \nu(Q[p \mapsto O])$ and $|Q_0|_p < |Q|_p$; then we can apply the IH to prove the term is s.n.
- $Q_0[p \mapsto \text{where } \overline{B} \text{ do } \iota O]$, where $Q = Q_0 \oplus \iota$: this is similar to the case above. \square

Having proved that all the typing rules preserve reducibility, we obtain that all well-typed terms of $NRC_{\lambda\delta\iota}$ are strongly normalizing and, as a corollary, the same property holds for $NRC_{\lambda}(\text{Set}, \text{Bag})$.

Theorem 5.11. *If $\Gamma \vdash M : T$ in $NRC_{\lambda\delta\iota}$, then $M \in \mathcal{SN}$ in $NRC_{\lambda\delta\iota}$.*

Corollary 5.12. *If $\Gamma \vdash M : T$ in $NRC_{\lambda}(\text{Set}, \text{Bag})$, then $M \in \mathcal{SN}$ in $NRC_{\lambda}(\text{Set}, \text{Bag})$.*

6. RELATED WORK

This paper builds on a long line of research on normalization of comprehension queries, a model of query languages popularized over 25 years ago by Buneman et al. [BNTW95] and inspired by Trinder and Wadler’s work on comprehensions [TW89, Wad92]. Wong [Won96] proved conservativity via a strongly normalizing rewrite system, which was used in Kleisli [Won00], a functional query system, in which flat query expressions were normalized to SQL. Libkin and Wong [LW94, LW97] investigated conservativity in the presence of aggregates, internal generic functions, and bag operations, and demonstrated that bag operations can be expressed using nested comprehensions. However, their normalization results studied bag queries by translating to relational queries with aggregation, and did not consider higher-order queries, so they do not imply the normalization results for $NRC_{\lambda}(\text{Set}, \text{Bag})$ given here.

Cooper [Coo09b] first investigated query normalization (and hence conservativity) in the presence of higher-order functions. He gave a rewrite system showing how to normalize homogeneous (that is, pure set or pure bag) queries to eliminate intermediate occurrences of nesting or of function types. However, although Cooper claimed a proof (based on $\top\top$ -lifting [LS05]) and provided proof details in his PhD thesis [Coo09a], there unfortunately turned out to be a nontrivial lacuna in that proof, and this paper therefore (in our opinion) contains the first *complete* proof of normalization for higher-order queries, even for the homogeneous case. The problem we identified with Cooper’s technique, concerning the behaviour of instantiated continuations under reduction appears to be related to issues with composition rules in explicit substitution calculi [ACCL91]: such calculi are known to require a careful treatment of reduction for them to simultaneously preserve confluence and strong normalization (see [Mel95] for a counterexample); more recent explicit substitution calculi (e.g. [DG01, KL05]) often employ ideas from linear logic to ensure strong normalization is preserved: it is an interesting theoretical question to see whether our technique can be explained in similar terms.

Since the fundamental work of Wong and others on the Kleisli system, language-integrated query has gradually made its way into other systems, most notably Microsoft’s .NET framework languages C# and F# [MBB06], and the Web programming language Links [CLWY07]. Cheney et al. [CLW13] formally investigated the F# approach to language-integrated query and showed that normalization results due to Wong and Cooper could be adapted to improve it further; however, their work considered only homogeneous collections. In subsequent work, Cheney et al. [CLW14] showed how use normalization to perform *query shredding* for multiset queries, in which a query returning a type with n nested collections can be implemented by combining the results of n flat queries; this has been implemented in Links [CLWY07].

Higher-order relational queries have also been studied by Benedikt et al. [BPV15], where the focus was mostly on complexity of the evaluation and containment problems. Their calculus focuses on higher-order expressions composing operations over *flat* relational algebra operators only, where the base types are records listing the fields of the relations. Thus, modulo notational differences, their calculus is a sublanguage of *NRC*. In their setting, normalization up to β -reduction follows as a special case of normalization for typed lambda-calculus; in our setting the same approach would not work because collection and record types can be combined arbitrarily in *NRC* and normalization involves rules that nontrivially rearrange comprehensions and other collection operations.

Several recent efforts to formalize and reason about the semantics of SQL are complementary to our work. Guagliardo and Libkin [GL17] presented a semantics for SQL’s actual behaviour in the presence of set and multiset operators (including bag intersection and difference) as well as incomplete information (nulls), and related the expressiveness of this fragment of SQL with that of an algebra over bags with nulls. Chu et al. [CWCS17] presented a formalised semantics for reasoning about SQL (including set and bag semantics as well as aggregation/grouping, but excluding nulls) using nested relational queries in Coq, while Benzaken and Contejean [BC19] presented a semantics including all of these SQL features (set, multiset, aggregation/grouping, nulls), and formalized the semantics in Coq. Kiselyov et al. [KK17] has proposed language-integrated query techniques that handle sorting operations (SQL’s `ORDER BY`).

However, the above work on semantics has not considered query normalization, and to the best of our knowledge normalization results for query languages with more than one collection type were previously unknown even in the first-order case. We are interested in extending our results for mixed set and bag semantics to handle nulls, grouping/aggregation, and sorting, thus extending higher-order language integrated query to cover all of the most widely-used SQL features. Normalization of higher-order queries in the presence of all of these features simultaneously remains an open problem, which we plan to consider next. In addition, fully formalizing such normalization proofs also appears to be a nontrivial challenge.

7. CONCLUSIONS

Integrating database queries into programming languages has many benefits, such as type safety and avoidance of common SQL injection attacks, but also imposes limitations that prevent programmers from constructing queries dynamically as they could by concatenating SQL strings unsafely. Previous work has demonstrated that many useful dynamic queries can be constructed safely using *higher-order functions* inside language-integrated queries;

provided such functions are not recursive, it was believed, query expressions can be normalized. Moreover, while it is common in practice for language-integrated query systems to provide support for SQL features such as mixed set and bag operators, it is not well understood in theory how to normalize these queries in the presence of higher-order functions. Previous work on higher-order query normalization has considered only homogeneous (that is, pure set or pure bag) queries, and in the process of attempting to generalize this work to a heterogeneous setting, we discovered a nontrivial gap in the previous proof of strong normalization. We therefore prove strong normalization for both homogeneous and heterogeneous queries for the first time.

As next steps, we intend to extend the Links implementation of language-integrated query with heterogeneous queries and normalization, and to investigate (higher-order) query normalization and conservativity for the remaining common SQL features, such as nulls, grouping/aggregation, and ordering.

APPENDIX A. PROOFS

This appendix expands on some results whose proofs were omitted or only sketched in the paper.

Proof of Lemma 4.2. If $K \in \mathcal{SN}$ is a continuation, then for all indices p we have $K[p \mapsto \emptyset] \in \mathcal{SN}$.

We proceed by well-founded induction, using the metric:

$$(K_1, p_1) \prec (K_2, p_2) \iff (\nu(K_1), \|K_1\|_{p_1}) \prec (\nu(K_2), \|K_2\|_{p_2})$$

- $K'[p \mapsto \emptyset]^\sigma$, where $K \rightsquigarrow^\sigma K'$: by Corollary 3.26, we need to show $K'[q \mapsto \emptyset] \in \mathcal{SN}$ whenever $\sigma(q) = p$; this follows from the IH, with $\nu(K') < \nu(K)$ by Lemma 3.11.
- $K_0[p \mapsto \emptyset]$, where $K = K_0 \textcircled{p} F$ for some frame F : by Lemma 3.12 we have $\nu(K_0) \leq \nu(K)$; furthermore, we can easily prove that $\|K_0\|_p < \|K\|_p$; then the thesis follows immediately from the IH. \square

Proof of Lemma 4.4. For all Q -continuations Q, O_1, O_2 with pairwise disjoint supports, if $Q[p \mapsto O_1] \in \mathcal{SN}$ and $Q[p \mapsto O_2] \in \mathcal{SN}$, then $Q[p \mapsto O_1 \cup O_2] \in \mathcal{SN}$.

We assume $p \in \text{supp}(Q)$ (otherwise, $Q[p \mapsto O_1] = Q[p \mapsto O_2] = Q[p \mapsto O_1 \cup O_2]$, and the thesis holds trivially). Then, by Lemma 3.9, $Q[p \mapsto O_1] \in \mathcal{SN}$ and $Q[p \mapsto O_2] \in \mathcal{SN}$ imply $Q \in \mathcal{SN}$, $O_1 \in \mathcal{SN}$, and $O_2 \in \mathcal{SN}$: thus we can proceed by well-founded induction on (Q, p, O_1, O_2) using the following metric:

$$\begin{aligned} (Q^1, p^1, O_1^1, O_2^1) \prec (Q^2, p^2, O_1^2, O_2^2) \\ \iff (\nu(Q^1), \|Q^1\|_{p^1}, \nu(O_1^1) + \nu(O_2^1)) \prec (\nu(Q^2), \|Q^2\|_{p^2}, \nu(O_1^2) + \nu(O_2^2)) \end{aligned}$$

to prove that if $Q[p \mapsto O_1] \in \mathcal{SN}$ and $Q[p \mapsto O_2] \in \mathcal{SN}$, then $Q[p \mapsto O_1 \cup O_2] \in \mathcal{SN}$. Equivalently, we will consider all possible contracta and show that each of them must be a strongly normalizing term; we will apply the induction hypothesis to new auxiliary continuations obtained by placing pieces of Q into O_1 and O_2 : the hypothesis on the supports of the continuations being disjoint is used to make sure that the new continuations do not contain duplicate holes and are thus well-formed. By cases on the possible contracta:

- $Q_1[q \mapsto Q_2 [\overline{L}/x]][p \mapsto (O_1 [\overline{L}/x]) \cup (O_2 [\overline{L}/x])]$ (where $Q = (Q_1 \textcircled{q} \bigcup \{x \leftarrow \{\overline{L}\}\})[q \mapsto Q_2]$, $q \in \text{supp}(Q_1)$, $p \in \text{supp}(Q_2)$): let $Q' = Q_1[q \mapsto Q_2 [\overline{L}/x]]$, and note that $Q \rightsquigarrow Q'$, hence $\nu(Q') < \nu(Q)$; note $Q[p \mapsto O_1] \rightsquigarrow Q'[p \mapsto O_1 [\overline{L}/x]]$, hence since the former term is s.n., so must be the latter, and hence also $O_1 [\overline{L}/x] \in \mathcal{SN}$; similarly, $O_2 [\overline{L}/x] \in \mathcal{SN}$; then we can apply the IH with $(Q', p, O_1 [\overline{L}/x], O_2 [\overline{L}/x])$ to obtain the thesis.
- $Q'[p \mapsto O_1 \cup O_2]^\sigma$ (where $Q \rightsquigarrow^\sigma Q'$): by Corollary 3.26, we need to prove that, for all q s.t. $\sigma(q) = p$, $Q'[q \mapsto O_1 \cup O_2] \in \mathcal{SN}$; since $Q[p \mapsto O_1] \in \mathcal{SN}$, we also have $Q'[p \mapsto O_1]^\sigma \in \mathcal{SN}$, which implies $Q'[q \mapsto O_1] \in \mathcal{SN}$ by Corollary 3.26; for the same reason, $Q'[q \mapsto O_2] \in \mathcal{SN}$; by Lemma 3.11, $\nu(Q') < \nu(Q)$, thus the thesis follows by IH.
- $Q_1[p \mapsto (\bigcup \{Q_2|x \leftarrow O_1\}) \cup (\bigcup \{Q_2|x \leftarrow O_2\})]$ (where $Q = Q_1 \textcircled{p} \bigcup \{Q_2|x\}$): by Lemma 3.12, $\nu(Q_1) \leq \nu(Q)$; we also know $\|Q_1\|_p < \|Q\|_p$; take $O'_1 := \bigcup \{Q_2|x \leftarrow O_1\}$ and note that, since $Q[p \mapsto O_1] = Q_0[p \mapsto O'_1]$, we have O'_1 is a subterm of a strongly normalizing term, thus $O'_1 \in \mathcal{SN}$; similarly, we define $O'_2 := \bigcup \{Q_2|x \leftarrow O_2\}$ and show it is s.n. in a similar way; then (Q_1, p, O'_1, O'_2) reduce the metric, and we can prove the thesis by IH.

- $Q_1[p \mapsto (\bigcup\{O_1|x \leftarrow Q_2\}) \cup (\bigcup\{O_2|x \leftarrow Q_2\})]$ (where $Q = Q_1 \oplus \bigcup\{x \leftarrow Q_2\}$): by Lemma 3.12, $\nu(Q_1) \leq \nu(Q)$; we also know $\|Q_1\|_p < \|Q\|_p$; take $O'_1 := \bigcup\{O_1|x \leftarrow Q_2\}$ and note that, since $Q[p \mapsto O_1] = Q_1[p \mapsto O'_1]$, we have O'_1 is a subterm of a strongly normalizing term, thus $O'_1 \in \mathcal{SN}$; similarly, we define $O'_2 := \bigcup\{O_2|x \leftarrow Q_2\}$ and show it is s.n. in a similar way; then (Q_1, p, O'_1, O'_2) reduce the metric, and we can prove the thesis by IH.
- $Q_0[p \mapsto (\text{where } \overline{B} \text{ do } O_1) \cup (\text{where } \overline{B} \text{ do } O_2)]$ (where $Q = Q_0 \oplus \text{where } \overline{B}$): by Lemma 3.12, $\nu(Q_0) \leq \nu(Q)$; we also know $\|Q_0\|_p < \|Q\|_p$; take $O'_1 := \text{where } B \text{ do } O_1$ and note that, since $Q[p \mapsto O_1] = Q_0[p \mapsto O'_1]$, we have O'_1 is a subterm of a strongly normalizing term, thus $O'_1 \in \mathcal{SN}$; similarly, we define $O'_2 := \text{where } \overline{B} \text{ do } O_2$ and prove it is strongly normalizing in the same way; then (Q_0, p, O'_1, O'_2) reduce the metric, and we can prove the thesis by IH.
- Contractions within O_1 or O_2 reduce $\nu(O_1) + \nu(O_2)$, thus the thesis follows by IH. \square

Reducibility for conditionals similarly to comprehensions. However, to consider all the conversions commuting with **where**, we need to use the more general auxiliary continuations, along with an auxiliary result that mirrors Lemma 4.4.

Lemma A.1. *If $Q[p \mapsto M \cup N] \in \mathcal{SN}$, then $Q[p \mapsto M] \in \mathcal{SN}$ and $Q[p \mapsto N] \in \mathcal{SN}$; furthermore, we have:*

$$\begin{aligned} \nu(Q[p \mapsto M]) &\leq \nu(Q[p \mapsto M \cup N]) \\ \nu(Q[p \mapsto N]) &\leq \nu(Q[p \mapsto M \cup N]) \end{aligned}$$

Proof. We assume $p \in \text{supp}(Q)$ (otherwise, $Q[p \mapsto M] = Q[p \mapsto N] = Q[p \mapsto M \cup N]$, and the thesis holds trivially), then we show that any contraction in $Q[p \mapsto M]$ has a corresponding non-empty reduction sequence in $Q[p \mapsto M \cup N]$, and the two reductions preserve the term form, therefore no reduction sequence of $Q[p \mapsto M]$ is longer than the maximal one in $Q[p \mapsto M \cup N]$. The same reasoning applies to $Q[p \mapsto N]$. \square

Proof of Lemma 4.8. Suppose $Q[p \mapsto \text{where } B \text{ do } M] \in \mathcal{SN}$. Then for all $B' \in \mathcal{SN}$ such that $\text{BV}(Q)$ and $\text{FV}(B')$ are disjoint, $Q[p \mapsto \text{where } B \wedge B' \text{ do } M] \in \mathcal{SN}$.

We proceed by well-founded induction on (Q, B, B', M, p) using the following metric:

$$\begin{aligned} (Q_1, B_1, B'_1, M_1, p_1) \prec (Q_2, B_2, B'_2, M_2, p_2) &\iff \\ (\nu(Q_1[p_1 \mapsto \text{where } B_1 \text{ do } M_1]), \nu(B'_1), \text{size}(M_1)) & \\ \prec (\nu(Q_2[p_2 \mapsto \text{where } B_2 \text{ do } M_2]), \nu(B'_2), \text{size}(M_2)) & \end{aligned}$$

We will consider all possible contracta of $Q[p \mapsto \text{where } B \wedge B' \text{ do } M]$ and show that each of them must be a strongly normalizing term. By cases:

- $Q_1[q \mapsto Q_2 [\overline{L}/x]][p \mapsto (\text{where } B \wedge B' \text{ do } M) [\overline{L}/x]]$, where $Q = (Q_1 \oplus \bigcup\{x \leftarrow \{\overline{L}\}\})[q \mapsto Q_2]$, $q \in \text{supp}(Q_1)$, and $p \in \text{supp}(Q_2)$; by the freshness condition we know $x \notin \text{FV}(B')$, thus $(\text{where } B \wedge B' \text{ do } M) [\overline{L}/x] = \text{where } B [\overline{L}/x] \wedge B' \text{ do } (O [\overline{L}/x])$; to apply the IH, we need to show $\nu(Q_1[q \mapsto Q_2 [\overline{L}/x]][p \mapsto \text{where } B [\overline{L}/x] \text{ do } M]) < \nu(Q[p \mapsto \text{where } B \text{ do } M])$: since the former term is a contractum of the latter, this is implied by Lemma 3.11.
- $Q'[p \mapsto \text{where } B \wedge B' \text{ do } M]^\sigma$, where $Q \xrightarrow{\sigma} Q'$. By Corollary 3.26, it suffices to prove $Q'[p \mapsto \text{where } B \wedge B' \text{ do } M]$ for all q s.t. $\sigma(p) = q$; we prove $\nu(Q'[q \mapsto \text{where } B \text{ do } M]) \leq \nu(Q'[p \mapsto \text{where } B \text{ do } M]^\sigma)$ (by Corollary 3.26), and $\nu(Q'[p \mapsto \text{where } B \text{ do } M]^\sigma) <$

- $\nu(Q[p \mapsto \text{where } B \text{ do } M])$ (by Lemma 3.11, since the former term is a contractum of the latter); then the thesis follows by IH.
- $Q_1[p \mapsto \text{where } B \wedge B' \text{ do } \bigcup\{Q_2|x \leftarrow M\}]$, where $Q = Q_1 \oplus \bigcup\{Q_2|x\}$; to apply the IH, we need to show $\nu(Q_1[p \mapsto \text{where } B \text{ do } \bigcup\{Q_2|x \leftarrow M\}]) < \nu(Q[p \mapsto \text{where } B \text{ do } M])$: since the former term is a contractum of the latter, this is implied by Lemma 3.11.
 - $Q_0[p \mapsto \text{where } B_0 \wedge B \wedge B' \text{ do } O]$, where $Q = Q_0 \oplus \text{where } B_0$; to apply the IH, we need to show $\nu(Q_1[p \mapsto \text{where } B_0 \wedge B \text{ do } M]) < \nu(Q[p \mapsto \text{where } B \text{ do } M])$: since the former term is a contractum of the latter, this is implied by Lemma 3.11.
 - $Q[p \mapsto \emptyset]$, where $O = \emptyset$: this term is also a contractum of $Q[p \mapsto \text{where } B \text{ do } \emptyset]$, thus it is strongly normalising.
 - $Q[p \mapsto (\text{where } B \wedge B' \text{ do } M_1) \cup (\text{where } B \wedge B' \text{ do } M_2)]$, where $M = M_1 \cup M_2$; we note that, for $i = 1, 2$, we have $\nu(Q[p \mapsto \text{where } B \text{ do } M_i]) \leq \nu(Q[p \mapsto (\text{where } B \text{ do } M_1) \cup (\text{where } B \text{ do } M_2)]) < \nu(Q[p \mapsto \text{where } B \text{ do } M])$, where the first inequality is by Lemma A.1, and the second by Lemma 3.11; we also note $\text{size}(M_i) < \text{size}(M)$; then we can apply the IH to prove $Q[p \mapsto \text{where } B \wedge B' \text{ do } M_i] \in \mathcal{SN}$, which implies the thesis by Lemma 4.4.
 - $(Q \oplus \bigcup\{x \leftarrow M_2\})[p \mapsto \text{where } B \wedge B' \text{ do } M_1]$, where $M = \bigcup\{M_1|x \leftarrow M_2\}$; to apply the IH, we need to show $\nu((Q \oplus \bigcup\{x \leftarrow M_2\})[p \mapsto \text{where } B \text{ do } M_1]) < \nu(Q[p \mapsto \text{where } B \text{ do } M])$: since the former is a contractum of the latter, this is implied by Lemma 3.11.
 - $Q[p \mapsto \text{where } B \wedge B' \wedge B_0 \text{ do } M_0]$, where $M = \text{where } B_0 \text{ do } M_0$; to apply the IH, we need to show $\nu(Q[p \mapsto \text{where } B \wedge B_0 \text{ do } M_0]) < \nu(Q[p \mapsto \text{where } B \text{ do } M])$: since the former is a contractum of the latter, this is implied by Lemma 3.11.
 - Reductions within B or M make the induction metric smaller, thus follow immediately from the IH. \square
