SUMMABILITY METHODS FOR INDEPENDENT, IDENTICALLY DISTRIBUTED RANDOM VARIABLES¹

TZE LEUNG LAI

ABSTRACT. In this paper, we present certain theorems concerning the Cesaro (C, α) , Abel (A) , Euler (E, q) and Borel (B) summability of $\sum Y_i$, where $Y_i = X_i - X_{i-1}$, $X_0 = 0$ and X_1, X_2, \dots are i.i.d. random variables. While the Kolmogorov strong law of large numbers and the Hartman-Wintner law of the iterated logarithm are related to $(C, 1)$ summability and involve the finiteness of, respectively, the first and second moments of X_1 , their analogues for Euler and Borel summability involve different moment conditions, and the analogues for (C, α) and Abel summability remain essentially the same.

Let X_1, X_2, \dots be independent, identically distributed (i.i.d.) random variables. Let $Y_n = X_n - X_{n-1}$ ($X_0 = Y_0 = 0$). Kolmogorov's strong law of large numbers asserts that $EX_1 = \mu$ iff $\sum Y_i$ is a.e. $(C, 1)$ summable to μ , i.e., the $(C, 1)$ limit of X_n is μ a.e. By the well-known inclusion theorems involving Cesaro and Abel summability (cf. [5, Theorems 43 and 55]), this implies that $\sum Y_i$ is a.e. (C, α) summable to μ for any $\alpha \geq 1$ and that $\sum Y_i$ is a.e. (A) summable to μ . In fact, the converse also holds in the present case, and we have the following theorem.

Theorem 1. *If X_1, X_2, \dots is a sequence of i.i.d. random variables and $\alpha \geq 1$ and μ are given real numbers, then the following statements are equivalent:*

- (1) $EX_1 = \mu$.
- (2) $X_n \rightarrow \mu(C, 1)$ a.e., i.e., $\lim_{n \rightarrow \infty} (1/n)(X_1 + \dots + X_n) = \mu$ a.e.
- (3) $X_n \rightarrow \mu(C, \alpha)$ a.e., i.e., $\lim_{n \rightarrow \infty} \sum_{i=1}^{n-1} \binom{i+\alpha-1}{i} X_{n-i} / \binom{n+\alpha}{n} = \mu$ a.e.,
 where $\binom{i+\beta}{j} = (\beta+1) \dots (\beta+j)/(j!)$.
- (4) $X_n \rightarrow \mu(A)$ a.e., i.e., $\lim_{\lambda \rightarrow 1^-} (1-\lambda) \sum_{i=1}^{\infty} \lambda^i X_i = \mu$ a.e.

Proof. The implications $(2) \Rightarrow (3) \Rightarrow (4)$ are well known (cf. [5, pp. 96, 100, 108]). We shall now prove that $(4) \Rightarrow (1)$. By (4),

$$\lim_{m \rightarrow \infty} \frac{1}{m} \sum_{n=1}^{\infty} e^{-n/m} X_n^s = 0 \quad \text{a.e.},$$

where $X_n^s = X_n - X'_n$ with $X'_n, n \geq 1$, and $X_n, n \geq 1$, being i.i.d. Let

$$Y_m = \frac{1}{m} \sum_{n=1}^m e^{-n/m} X_n^s, \quad Z_m = \frac{1}{m} \sum_{n=m+1}^{\infty} e^{-n/m} X_n^s.$$

Then $Y_m + Z_m \xrightarrow{P} 0$, Y_m and Z_m are independent and symmetric. Therefore it follows easily from the Lévy inequality [8, p. 247] that $Z_m \xrightarrow{P} 0$. Since Z_m and (Y_1, \dots, Y_m) are independent and $Y_m + Z_m \rightarrow 0$ a.e., $Z_m \xrightarrow{P} 0$, we obtain by Lemma 3 of [2] that $Y_m \rightarrow 0$ a.e. Letting $Y_m^{(1)} = Y_m - (em)^{-1} X_m^s$, since $(em)^{-1} X_m^s \xrightarrow{P} 0$, we again obtain by Lemma 3 of [2] that $X_m^s/m \rightarrow 0$ a.e. By the Borel-Cantelli lemma, this implies that $E|X_1| < \infty$. As established before, we then have $X_n \rightarrow EX_1(A)$ and so by (4), $\mu = EX_1$.

The classical law of the iterated logarithm gives us the rate at which the convergence in (2) takes place. Gaposhkin [4] has established the law of the iterated logarithm for the (C, α) and Abel methods in the case where X_1 is bounded. Actually by using either the Hartman-Wintner truncation scheme [6] or Strassen's strong invariance principle [9], we can extend Gaposhkin's results to the case where $0 < EX_1^2 < \infty$. The extension is the sharpest possible in the sense that its converse also holds, and this converse can be established by a modification of Feller's argument in [3]. The details of the proof are omitted here, and we simply state the results in the following theorem.

Theorem 2. *With the same notation as in Theorem 1, for any given positive number σ , the following statements are equivalent:*

- (5) $EX_1 = 0, EX_1^2 = \sigma^2$.
- (6) $\limsup_{n \rightarrow \infty} |\sum_{i=1}^n X_i| / \{2n \log \log n\}^{1/2} = \sigma$ a.e.
- (7) $\limsup_{n \rightarrow \infty} |\sum_{i=1}^n \binom{i+\alpha-1}{i} X_{n-i}| / \{2n^{2\alpha-1} \log \log n\}^{1/2} = \sigma / \{(2\alpha-1)^{1/2} \Gamma(\alpha)\}$ a.e.
- (8) $\limsup_{\lambda \rightarrow 1-} (1-\lambda)^{1/2} |\sum_{i=1}^{\infty} \lambda^i X_i| / \{|\log | \log (1-\lambda) |\}^{1/2} = \sigma$ a.e.

Our primary interest in this paper lies in the analogue of the law of the iterated logarithm for the Euler and Borel methods of summation (cf. [5,

Chapters 8 and 9]). Chow [1] has shown that unlike the Cesaro and Abel methods which require $E|X_1| < \infty$ for summability, the Euler and Borel methods require $EX_1^2 < \infty$ for summability. Specifically, if X_1, X_2, \dots are i.i.d., then the following statements are equivalent:

$$(9) EX_1 = \mu, EX_1^2 < \infty.$$

$$(10) X_n \rightarrow \mu(E, q) \text{ for some (or equivalently for every) } q > 0, \text{ i.e.,}$$

$$\lim_{n \rightarrow \infty} (q+1)^{-n} \sum_{i=1}^n \binom{n}{i} q^{n-i} X_i = \mu \quad \text{a.e.}$$

$$(11) X_n \rightarrow \mu(B), \text{ i.e.,}$$

$$\lim_{\lambda \rightarrow \infty} e^{-\lambda} \sum_{i=1}^{\infty} \frac{\lambda^i}{i!} X_i = \mu \quad \text{a.e.}$$

The following theorem gives the rate at which the convergence in (10) or (11) takes place. It is interesting to compare the result with Theorem 2.

Theorem 3. Suppose $q > 0, \sigma > 0$ and X_1, X_2, \dots are i.i.d. random variables. Then the following statements are equivalent:

$$(12) EX_1 = 0, EX_1^2 = \sigma^2, EX_1^4(\log^+ |X_1| + 1)^{-2} < \infty.$$

$$(13) \limsup_{\lambda \rightarrow \infty} (\pi\lambda)^{1/4} (\log \lambda)^{-1/2} \left| \sum_{i=1}^{\infty} e^{-\lambda} (\lambda^i / i!) X_i \right| = \sigma / \sqrt{2} \text{ a.e.}$$

$$(14) \limsup_{n \rightarrow \infty} (\pi q n)^{1/4} (\log n)^{-1/2} \left| \sum_{i=1}^n (q+1)^{-n} \binom{n}{i} q^{n-i} X_i \right| = \sigma (\tfrac{1}{2}(q+1))^{1/2} \text{ a.e.}$$

Lemma. Let X_1, X_2, \dots be independent random variables with $EX_n = 0, EX_n^2 = \sigma_n^2$ and $\lim_{n \rightarrow \infty} \sigma_n^2 = \sigma^2 > 0$. Suppose for $j \geq j_0$, there exists $r_j \geq 0$ such that $r_j = o(j^{1/4} (\log j)^{-1/2})$ and

$$(15) \exp\{t^2 \sigma_j^2 (1 - |t| r_j) / 2\} \leq E \exp(t X_j) \leq \exp\{t^2 \sigma_j^2 (1 + |t| r_j / 2) / 2\}$$

whenever $|t| r_j \leq 1$. Then for any $c > 0$ and $\alpha > 1/2$,

$$(16) \limsup_{M \rightarrow \infty} \left(\frac{\pi M}{2c} \right)^{-1/4} (\log M)^{-1/2} \sum_{|m-M| \leq M^\alpha} X_m \exp \left(\frac{-c(m-M)^2}{M} \right) = \sigma \quad \text{a.e.}$$

Proof. To simplify the notation, we shall set $h = m - M$. Let $0 < \delta < \delta' < 1$ such that $(1 - \delta')^2 (1 + \delta) < 1$. Choose $\zeta > 1$ such that

$$\delta > 3 \left(2 \int_{\zeta}^{\infty} e^{-2ct^2} dt \right)^{1/2} \quad \text{and} \quad \int_{-\zeta}^{\zeta} e^{-2ct^2} dt > (1 - \delta)^2 (\pi / 2c)^{1/2}.$$

Let

$$s_M^2 = \sum_{\zeta\sqrt{M} < |h| \leq M^\alpha} (\exp(-2ch^2/M)) \sigma_m^2 \sim 2\sigma^2\sqrt{M} \int_{\zeta}^{\infty} \exp(-2ct^2) dt,$$

$$Y_M = \left(\frac{1}{s_M}\right) \sum_{\zeta\sqrt{M} < |h| \leq M^\alpha} (\exp(-ch^2/M)) X_m.$$

Using (15) and Kolmogorov's (upper) exponential bounds (cf. [10, Lemma 1]), we obtain that for all large M ,

$$(17) \quad P \left[\sum_{\zeta\sqrt{M} < |h| \leq M^\alpha} (\exp(-ch^2/M)) X_m \geq \delta \sigma M^{1/4} (\log M)^{1/2} \right] \\ \leq P[Y_M \geq 3(\log M)^{1/2}] \leq \exp\{-(9/4) \log M\}.$$

Replacing X_m by $-X_m$ in (17) gives a similar inequality, and an application of the Borel-Cantelli lemma gives

$$(18) \quad \limsup_{M \rightarrow \infty} M^{-1/4} (\log M)^{-1/2} \left| \sum_{\zeta\sqrt{M} < |h| \leq M^\alpha} (\exp(-ch^2/M)) X_m \right| \leq \delta \sigma \text{ a.e.}$$

Choose $\eta > \zeta^2$ and set $m_k = [\eta k^2]$. Using (15) and Kolmogorov's (lower) exponential bounds (cf. [10, Lemma 1]), it can be shown that for all large k ,

$$(19) \quad P \left[\left(\frac{\pi m_k}{2c} \right)^{-1/4} \sum_{|h| \leq \zeta\sqrt{m_k}} X_m \exp \left(\frac{-ch^2}{m_k} \right) \geq (1 - \delta) \sigma (2 \log k)^{1/2} \right] \\ \geq \exp\{-(1 + \delta)(1 - \delta')^2 \log k\}.$$

Now the σ -fields $\mathcal{F}_k = \mathcal{B}(X_m : |m - m_k| \leq \zeta\sqrt{m_k})$ are independent for all large k . Hence it follows from (19) and the Borel-Cantelli lemma that

$$(20) \quad \limsup_{k \rightarrow \infty} \left(\frac{\pi m_k}{2c} \right)^{-1/4} (2 \log k)^{-1/2} \sum_{|h| \leq \zeta\sqrt{m_k}} X_m \exp \left(\frac{-ch^2}{m_k} \right) \geq (1 - \delta) \sigma \text{ a.e.}$$

Since $2 \log k \sim \log m_k$ and δ is arbitrary, we obtain from (18) and (20) that the \limsup in (16) is $\geq \sigma$ a.e.

To prove that the \limsup in (16) is $\leq \sigma$ a.e., let $\eta_k = (\log k)^{-2}$, $M_k = [\eta_k k^2]$. An application of Kolmogorov's (upper) exponential bounds gives

$$(21) \sum P \left[\left(\frac{\pi M_k}{2c} \right)^{-1/4} \sum_{|b| \leq \zeta \sqrt{M_k}} X_m \exp \left(\frac{-cb^2}{M_k} \right) \geq (1 + \delta) \sigma (2 \log k)^{1/2} \right] < \infty.$$

Obviously (21) still holds with X_m replaced by $-X_m$, and noting that $\log M_k \sim 2 \log k$, we obtain that

$$(22) \limsup_{k \rightarrow \infty} \left(\frac{\pi M_k}{2c} \right)^{-1/4} (\log M_k)^{-1/2} \left| \sum_{|b| \leq \zeta \sqrt{M_k}} X_m \exp \left(\frac{-cb^2}{M_k} \right) \right| \leq (1 + \delta) \sigma \quad \text{a.e.}$$

We now assert that

$$(23) \limsup_{k \rightarrow \infty} M_k^{-1/4} (\log M_k)^{-1/2} \max_{M_k < M \leq M_{k+1}} |U_{k,M}| \leq 6\delta \quad \text{a.e.,}$$

where we define, for $M_k < M \leq M_{k+1}$,

$$U_{k,M} = \sum_{|m-M| \leq \zeta \sqrt{M}} X_m \exp \left(\frac{-c(m-M)^2}{M} \right) - \sum_{|m-M_k| \leq \zeta \sqrt{M_k}} X_m \exp \left(\frac{-c(m-M_k)^2}{M_k} \right);$$

$$U_{k,M}^{(1)} = \sum_{M_k - \zeta \sqrt{M_k} \leq m < M - \zeta \sqrt{M}} X_m \exp \left(\frac{-c(m-M_k)^2}{M_k} \right);$$

$$U_{k,M}^{(2)} = \sum_{M - \zeta \sqrt{M} \leq m < M_k} X_m \left\{ \exp \left(\frac{-c(m-M_k)^2}{M_k} \right) - \exp \left(\frac{-c(m-M)^2}{M} \right) \right\};$$

$$U_{k,M}^{(3)} = \sum_{M_k \leq m < M} X_m \exp \left(\frac{-c(m-M_k)^2}{M_k} \right);$$

$$U_{k,M}^{(4)} = \sum_{M_k \leq m < M} X_m \exp \left(\frac{-c(m-M)^2}{M} \right);$$

$$U_{k,M}^{(5)} = \sum_{M \leq m < M_k + \zeta \sqrt{M_k}} X_m \left\{ \exp \left(\frac{-c(m-M)^2}{M} \right) - \exp \left(\frac{-c(m-M_k)^2}{M_k} \right) \right\};$$

$$U_{k,M}^{(6)} = \sum_{M_k + \zeta \sqrt{M_k} \leq m \leq M + \zeta \sqrt{M}} X_m \exp \left(\frac{-c(m-M)^2}{M} \right).$$

We note that if k is sufficiently large and $M_k < M \leq M_{k+1}$, then $M_k - \zeta \sqrt{M_k} < M - \zeta \sqrt{M} < M_k < M < M_k + \zeta \sqrt{M_k} < M + \zeta \sqrt{M}$, and so $|U_{k,M}| \leq \sum_{i=1}^6 |U_{k,M}^{(i)}|$.

First consider $U_{k,M}^{(1)}$. Setting $t = (8\delta^{-2} \log k)^{1/2}$, we have from (15) that

$$\begin{aligned}
 & P[U_{k,M}^{(1)} \geq \delta M_k^{1/4} (\log M_k)^{1/2}] \\
 & \leq \{ \exp(-t\delta(\log M_k)^{1/2}) \} E \exp\{tM_k^{-1/4} U_{k,M}^{(1)}\} \\
 (24) \quad & \leq k^{-4} \exp\left\{t^2 M_k^{-1/2} \sum_{M_k - \zeta\sqrt{M_k} \leq m < M - \zeta\sqrt{M}} \sigma_m^2 \exp\left(\frac{-2c(m - M_k)^2}{M_k}\right)\right\} \\
 & = O(k^{-4}).
 \end{aligned}$$

Replacing X_m by $-X_m$ in the above argument, we then obtain from (24) that

$$P\left[\max_{M_k < M \leq M_{k+1}} |U_{k,M}^{(1)}| \geq \delta M_k^{1/4} (\log M_k)^{1/2}\right] = O(k^{-4}(M_{k+1} - M_k)) = O(k^{-3}).$$

Therefore by the Borel-Cantelli lemma, we have for $i = 1$,

$$(25) \quad \limsup_{k \rightarrow \infty} M_k^{-1/4} (\log M_k)^{-1/2} \max_{M_k < M \leq M_{k+1}} |U_{k,M}^{(i)}| \leq \delta \quad \text{a.e.}$$

By a similar argument, we can show that (25) also holds for $i = 2, 3, 4, 5, 6$. Hence (23) holds, and the desired conclusion follows from (18), (22) and (23).

Proof of Theorem 3. We first assume (12) and show that (13) and (14) both hold. Set $b_m(\lambda) = e^{-\lambda} \lambda^{m/(m!)}$, let $1/2 < \alpha < 2/3$ and let k be an integer such that $k(1 - \alpha) > 1$. Given $\delta > 0$, we choose $\epsilon > 0$ such that $\epsilon k < \delta$. From (12), it follows that

$$(26) \quad \lim_{n \rightarrow \infty} n^{-1/4} (\log n)^{-1/2} X_n = 0 \quad \text{a.e.}$$

To prove (13), we set $M = [\lambda]$, $h = m - M$. Since there exists $\nu > 0$ such that $\sum_{|h| > M^\alpha} b_m(\lambda) = O(\exp(-\lambda^\nu))$ (cf. [5, p. 200]), it follows from (26) that

$$(27) \quad \lim_{\lambda \rightarrow \infty} \lambda^{1/4} (\log \lambda)^{-1/2} \sum_{|h| > M^\alpha} b_m(\lambda) |X_m| = 0 \quad \text{a.e.}$$

Furthermore we note that (cf. [5, p. 200])

$$\begin{aligned}
 & \sum_{|h| \leq M^\alpha} \left| (2\pi M)^{-1/2} \exp\left(\frac{-h^2}{2M}\right) - b_m(\lambda) \right| \\
 (28) \quad & = \sum_{|h| \leq M^\alpha} \left\{ (2\pi M)^{-1/2} \exp\left(\frac{-h^2}{2M}\right) \right\} \left\{ O\left(\frac{(1 + |h|)}{\lambda}\right) + O\left(\frac{|h|^3}{\lambda^2}\right) \right\} = O(\lambda^{-1/2})
 \end{aligned}$$

Hence it follows from (26) that

$$(29) \quad \lim_{\lambda \rightarrow \infty} \lambda^{1/4} (\log \lambda)^{-1/2} \left\{ \sum_{|b| \leq M^\alpha} \left| (2\pi M)^{-1/2} \exp\left(\frac{-b^2}{2M}\right) - b_m(\lambda) \right| |X_m| \right\} = 0 \quad \text{a.e.}$$

Define

$$X'_n = X_n I_{[|X_n| \geq \epsilon n^{1/4} (\log n)^{1/2}]}, \quad X''_n = X_n I_{[|X_n| \leq n^{1/4} / (\log n)]}$$

and $X'''_n = X_n - X'_n - X''_n$. Let $Y_n = X''_n - EX''_n$. Then $EY_n = 0$, $EY_n^2 = \sigma_n^2 \rightarrow \sigma^2$, $|Y_n| \leq 2n^{1/4} / (\log n) = o(n^{1/4} (\log n)^{-1/2})$ and therefore satisfies the hypothesis of the lemma (cf. [8, p. 255]). Hence

$$(30) \quad \limsup_{\lambda \rightarrow \infty} (\pi \lambda)^{-1/4} (\log \lambda)^{-1/2} \sum_{|b| \leq M^\alpha} Y_m \exp\left(\frac{-b^2}{2M}\right) = \sigma \quad \text{a.e.}$$

Noting that $EX_1 = 0$, we have for $|b| \leq M^\alpha$,

$$(31) \quad |EX''_m| = |EX_1 I_{[|X_1| > m^{1/4} / (\log m)]}| \leq m^{-1/2} (\log m)^2 E|X_1|^3.$$

Hence

$$\lim_{\lambda \rightarrow \infty} \lambda^{1/4} (\log \lambda)^{-1/2} \sum_{|b| \leq M^\alpha} \left(M^{-1/2} \exp\left(\frac{-b^2}{2M}\right) \right) |EX''_m| = 0.$$

Also by (26), $P[X'_n \neq 0 \text{ i.o.}] = 0$. Since $m^{1/4} / (\log m) < |X'''_m| < \epsilon m^{1/4} (\log m)^{1/2}$, we have for all large M ,

$$\begin{aligned} P \left[\sum_{|b| \leq M^\alpha} |X'''_m| \geq \delta M^{1/4} (\log M)^{1/2} \right] &\leq P \left[\sum_{|b| \leq M^\alpha} \frac{|X'''_m|}{(\epsilon m^{1/4} (\log m)^{1/2})} \geq k \right] \\ &\leq P[X'''_m \neq 0 \text{ for at least } k \text{ of the indices } M - M^\alpha \leq m \leq M + M^\alpha] \\ &\leq \binom{1 + 2[M^\alpha]}{k} P^k[|X_1|^4 > (M - M^\alpha) \{\log(M - M^\alpha)\}^{-4}] \\ &= O(M^{\alpha k - k} (\log M)^{6k}), \quad \text{by the Markov inequality.} \end{aligned}$$

Since $k - \alpha k > 1$, an application of the Borel-Cantelli lemma then gives

$$(32) \quad \limsup_{\lambda \rightarrow \infty} \lambda^{1/4} (\log \lambda)^{-1/2} \sum_{|b| \leq M^\alpha} M^{-1/2} |X'''_m| \leq \delta \quad \text{a.e.}$$

Hence we have proved (13). To prove (14), setting $M = [(n+1)/(q+1)]$, $c = (q+1)/2q$, we can use a similar argument as before (cf. [5, p. 201]).

We now prove that (13) implies (12). From (13), it is clear that $X_n \rightarrow 0(B)$ a.e. By the equivalence of (9) and (11), we have $EX_1 = 0$ and $EX_1^2 < \infty$. For $n = 3, 4, \dots$, let $d_m(n) = (\pi n)^{1/4} (\log n)^{-1/2} b_m(n)$, $Y_n = \sum_{m=1}^n d_m(n) X_m$, $Z_n = \sum_{m=n+1}^{\infty} d_m(n) X_m$. Since $EX_1 = 0$ and $EX_1^2 < \infty$, it follows from Tchebychev's inequality that $Z_n \xrightarrow{P} 0$. Now Z_n is independent of (Y_1, \dots, Y_n) and $\limsup_{n \rightarrow \infty} |Y_n + Z_n| = \sigma/\sqrt{2}$ a.e. Hence by Lemma 1 of [7], $\limsup_{n \rightarrow \infty} |Y_n| \leq \sigma/\sqrt{2}$ a.e. But $Y_n = \sum_{m=1}^{n-1} d_m(n) X_m + d_n(n) X_n$ and $d_n(n) X_n \xrightarrow{P} 0$. Therefore applying Lemma 1 of [7] again, we have

$$\limsup_{n \rightarrow \infty} \left| \sum_{m=1}^{n-1} d_m(n) X_m \right| \leq \frac{\sigma}{\sqrt{2}} \quad \text{a.e.}$$

and

$$\limsup_{n \rightarrow \infty} |d_n(n) X_n| \leq \sqrt{2}\sigma \quad \text{a.e.}$$

Hence

$$\limsup_{n \rightarrow \infty} n^{-1/4} (\log n)^{-1/2} |X_n| < \infty \quad \text{a.e.,}$$

and since this \limsup can only be ∞ a.e. of 0 a.e., it follows that $n^{-1/4} (\log n)^{-1/2} X_n \rightarrow 0$ a.e. Therefore $EX_1^4 (\log^+ |X_1| + 1)^{-2} < \infty$. It is now obvious from (13) that $EX_1^2 = \sigma^2$. In a similar way, we can prove that (14) implies (12).

Acknowledgment. I wish to thank Professor Y. S. Chow for his valuable suggestions and encouragement.
