SOLVING SEQUENTIAL CONDITIONS BY  
FINITE STATE STRATEGIES\*

J. Richard Buchi and Lawrence H. Landweber\*\*  
Purdue University, Lafayette, Indiana

Our main purpose is to present an algorithm which decides whether or not a condition  $C(X,Y)$  stated in sequential calculus admits a finite automata solution, and produces one if it exists. This solves a problem stated in [4] and contains, as a very special case, the answer to case 4 left open in [6]. In an equally appealing form the result can be restated in the terminology of [7,10,15]: Every  $\omega$ -game definable in sequential calculus is determined. Moreover the player who has a winning strategy, in fact, has a winning finite state strategy, that is one which can effectively be played in a strong sense. The main proof, that of the central Theorem 1, will be presented at the end. We begin with a discussion of its consequences. •

1. CONDITIONS ON SEQUENTIAL OPERATORS

Let  $C(X,Y)$  be a condition (i.e., binary relation) on  $\omega$ -sequences  $X = X_0, X_1, X_2, \dots$  and  $Y = Y_0, Y_1, Y_2, \dots$  of members of the finite sets  $I$  and  $J$ . Let  $Y=A(X)$  be an operator which maps  $I$ -sequences into  $J$ -sequences. We will say that the operator  $A$

---

\*This research was sponsored by the National Science Foundation (Contract 4730-50-395). The main result was announced in [13].

\*\* Presently at the University of Wisconsin, Madison Wisconsin.

solves the condition  $C(X,Y)$  for  $Y$  or that  $A$  is a solution of  $C$  for  $Y$ , if  $(\forall X) C(X,A(X))$  or equivalently,

$$(1) \quad (\forall XY) \cdot Y=A(X) \supset C(X,Y)$$

If no further requirement is imposed on solutions, then the axiom of choice states:  $(\forall X)(\exists Y)C(X,Y)$  is the solvability condition of  $C$  for  $Y$ . The solvability question becomes more interesting if one requires the solution  $A$  to be continuous in the sense of the natural Cantor topology on the set of all  $\omega$ -sequences over the alphabets  $I$  and  $J$ . Let  $I^*$  denote the set of all finite sequences (words) over  $I$ . The members of  $I^*$  form a tree if all words  $wa, a \in I$  are taken as direct successors of  $w \in I^*$ .  $\omega$ -sequences over  $I$  are represented by infinite paths through the tree. Let  $U_w$  be the set of all those paths  $X$  which contain  $w$  (as an initial segment). The finite unions  $U_{w_1} \dots U_{w_n}$  are then the open-closed sets of the totally disconnected space of all  $I$ -sequences. An operator  $Y=A(X)$  is continuous if it may be given in the form,

$$(2) \quad Yt = \Phi(\bar{X}(\phi t))$$

whereby  $\bar{X}z$  stands for the word  $X_0, \dots, X_z$ ,  $\phi$  is a map from  $\omega$  into  $\omega$  and  $\Phi$  maps  $I^*$  into  $J$ .

Among the continuous operators there are those for which the entries in the sequence  $Y=A(X)$  can in fact be computed, if sufficient information about the entries in  $X$  is provided. The recursive operators (RO) are those presentable in form (2), whereby both  $\phi$  and  $\Phi$  are recursive.

A particularly simple class of recursive operators are the finite automata operators (FAO), that is those operators which may be presented in the form,

$$\begin{aligned} Z_0 &= H[X_0] \\ (3) \quad Z_{t'} &= L[X_{t'}, Z_t] \\ Y_t &= W[Z_t] \end{aligned}$$

Here  $Z$  varies over  $\omega$ -sequences from a finite set  $K$ .  $H, L$  and  $W$  are functions from  $I$  into  $K$ ,  $I \times K$  into  $K$ , and  $K$  into  $J$ . A system  $\langle K, H, L, W \rangle$  is called a finite automaton with input states  $I$ , output states  $J$ , and (internal) states  $K$ . Finite automata were first studied by Kleene [12]. Also see [3,5,16]. Besides being recursive, FAO's are deterministic in the sense that the state of  $Y$  at time  $t$  can be calculated without anticipating future states of the input  $X$ . More precisely, a continuous operator (2) is deterministic (DO) if  $\phi t \leq t$ . I.e., if it can be given in the form,

$$(4) \quad Y_t = \phi(\bar{X}t)$$

Thus we use the term deterministic in the sense familiar from physics.

Note that a DO is continuous but need not be recursive.

A FAO is a recursive deterministic operator (RDO). Furthermore, one easily proves: The DO given by (4) is a FAO if and only if the right congruence  $u \sim v$  on words, defined by  $(\forall w) \phi(uw) = \phi(vw)$ , has finite index. This explains in just which way a finite automaton is limited in its ability to memorize the input history  $\bar{X}t$  at time  $t$ . To be a FAO is a very strong requirement on a RDO.

The operator (2) might be called n-shift in case  $\phi t = 0$  for  $t < h$ ,  $\phi t = t-h$  for  $h \leq t$ . The deterministic operators now appear as 0-shift  $\supseteq$  1-shift  $\supseteq$  2-shift  $\supseteq \dots$ . In particular (4) is a 0-shift operator and a 1-shift operator is one of form

$$(4') \quad Y_t = \phi(\bar{X}(t-1))$$

whereby  $\bar{X}(-1)$  stands for the **empty** word. Furthermore, the FAO defined by (3) is a 0-shift FAO, while a 1-shift FAO can always be presented in the form

$$(3') \quad \begin{aligned} Z_0 &= c \\ Z_{t'} &= L[X_t, Z_t] \\ Y_t &= W[Z_t] \end{aligned}$$

whereby  $c \in K$  is called the initial state of the 1-shift automaton  $\langle K, c, L, W \rangle$ .

DEFINITION 1. A condition  $C$  is called determined if, either there exists a 0-shift deterministic solution  $Y=A(X)$  of  $C(X,Y)$  for  $Y$  or else there exists a 1-shift deterministic solution  $X=B(Y)$  of  $\sim C(X,Y)$  for  $X$ .

It is interesting to contemplate this notion in the context of the Cantor topology; say for example, if  $C$  is a Borel set in the product of the two spaces. This is studied in a game theoretic context in [7,10,15]. If  $C$  is determined, it either contains the graph of a continuous function  $Y = A(X)$ , or else  $\sim C$  contains the graph of a continuous function  $X = B(Y)$ .

LEMMA 1. Let  $C$  be an arbitrary condition. There cannot both exist a 0-shift deterministic solution  $Y=A(X)$  of  $C(X,Y)$  for  $Y$  and a 1-shift deterministic solution  $X=B(Y)$  of  $\sim C(X,Y)$  for  $X$ .

PROOF. Suppose  $Y=A(X)$  is a 0-shift solution of  $C$  for  $Y$ , given by  $Y_t = \phi(\bar{X}t)$ , and  $X=B(Y)$  is a 1-shift solution of  $\sim C$  for  $X$ , given by  $X_t = \psi(\bar{Y}(t-1))$ . The system of equations  $Y_t = \phi(\bar{X}t)$ ,  $X_t = \psi(\bar{Y}(t-1))$  can be viewed as a simultaneous course-of-value induction, defining a pair  $X_0, Y_0$  satisfying both equations, for all values of  $t$ . But then  $Y_0 = A(X_0)$  and  $X_0 = B(Y_0)$ . Therefore, if  $A$  solves  $C$  for  $Y$  and  $B$  solves  $\sim C$  for  $X$ , we have  $C(X_0, Y_0)$  and  $\sim C(X_0, Y_0)$ , which is contradictory.

Q. E. D.

## 2. FINITE STATE CONDITIONS, THE $\omega$ -BEHAVIOR OF FINITE AUTOMATA

Let  $Z = E(X,Y)$  be a FAO from  $\omega$ -sequences on  $I \times J$  into  $\omega$ -sequences on  $S$ , given by the recursions,

$$\begin{aligned} Z_0 &= s_0 \\ (5) \quad Z_t &= H[X_t, Y_t, Z_t]. \end{aligned}$$

Here  $s_0$  is a member of  $S$  and  $H$  maps  $I \times J \times S$  into  $S$ . Furthermore, let  $U$  be a class of subsets of  $S$ , called the output condition. Let  $\text{sup } Z$  denote the set of all states taken infinitely often by  $Z$ . I.e.,

$$(6) \quad s \in \text{sup } Z \iff (\forall x)(\exists t)[x \leq t \wedge Z_t = s]$$

DEFINITION 2. The  $\omega$ -behavior of  $\langle S, s_0, H, U \rangle$  (of the FAO  $E$  with output condition  $U$ ) is the relation  $C(X, Y)$  which holds for  $X$  and  $Y$  if  $Z \equiv E(X, Y)$  satisfies  $\sup Z \in U$ . I.e.,

$$(7) \quad C(X, Y) \equiv (\exists Z)[Z_0 = s_0 \wedge (\forall t) Z_t' = H[X_t, Y_t, Z_t] \wedge \sup Z \in U]$$

By a finite state condition we mean one which is the  $\omega$ -behavior of some FAO with output condition. Our basic result may be stated thus,

THEOREM 1. For every finite state condition  $C(X, Y)$  is determined. Moreover, either there is a 0-shift FAO which solves  $C$  for  $Y$  or else there is a 1-shift FAO which solves  $\sim C$  for  $X$ .

The proof is contained in section 5. Actually we obtain there a constructive version of Theorem 1. In section 3 we discuss a game theoretic form of this theorem which was conjectured by McNaughton. The purpose of section 4 is to show that a surprisingly wide class of formulas  $C$  in fact define finite state conditions. We thereby extend the applicability of Theorem 1. An important step in this extension is provided by a recent result of McNaughton [14], which can truly be called the fundamental lemma of finite automata behavior. It can be stated as follows.

In place of the initial state  $s_0$  we assume a set of initial states  $K \subseteq S$ . In place of the function  $H$  from  $I \times J \times S$  into  $S$  we consider a relation  $L$  on  $I \times J \times S \times S$ . An  $\omega$ -sequence  $Z$  on  $S$  is called a transition sequence of the transition system (sometimes called non-deterministic finite automaton)  $\langle S, K, L \rangle$  if

$$(5') \quad \begin{aligned} &K[Z_0] \\ &L[X_t, Y_t, Z_t, Z_t'], \text{ for all } t. \end{aligned}$$

The notion of  $\omega$ -behavior naturally generalizes to transition systems. Namely ,

DEFINITION 2'. The  $\omega$ -behavior of the transition system  $\langle S, K, L, U \rangle$  with output condition is the relation  $C(X, Y)$  which holds for  $X$  and  $Y$  if there is a transition sequence  $Z$  such that  $\sup Z \in U$ . I.e.,

$$(7') \quad C(X, Y) \equiv (\exists Z)[K[Z_0] \wedge (\forall t)L[X_t, Y_t, Z_t, Z_{t+1}] \wedge \sup Z \in U]$$

The fundamental lemma now states that  $\omega$ -behaviors of transition systems are still finite state conditions. More precisely,

FUNDAMENTAL LEMMA (McNaughton). To every transition system with output condition  $L = \langle S, K, L, U \rangle$  on the input states  $I \times J$  one can effectively construct a finite automaton with output condition  $H = \langle S', s_0, H, W \rangle$  on  $I \times J$ , such that  $L$  and  $H$  have the same  $\omega$ -behavior.

Thus Theorem 1 remains true if  $C(X, Y)$  is the  $\omega$ -behavior of a transition system. A further extension is discussed in section 4.

### 3. $\omega$ -GAMES AND SEQUENTIAL CONDITIONS

McNaughton has observed a close relationship between the notion of a deterministic solution of a condition  $C(X, Y)$  and that of a winning strategy in purely combinatorial  $\omega$ -games studied in the literature [7,10,15]. While this game terminology is not really needed for our purpose, it puts both the solvability problems of automata theory and game theory into a wider context, and adds appealing flavors to each. For example, the notion of determinateness (Definition 1) is very natural in terms of games, but did not

arrive independently in automata theory. Indeed we could have avoided all reference to solutions of  $\sim C(X,Y)$  for  $X$ , in a presentation of our solvability algorithm. But this would clearly be hiding important information.

A condition  $C(X,Y)$  can be viewed as a game for two, player I and player J. Intuitively, a play of the game  $C(X,Y)$  goes as follows. At any time  $t = 0, 1, 2, \dots$  player I makes a move  $X_t$  by selecting a member of  $I$ . Then player J follows up with a move  $Y_t$  from  $J$ . The play  $\langle X, Y \rangle$  is completed when all  $\omega$  moves  $X_0, Y_0, X_1, Y_1, \dots$  have been made. Player J wins if  $C(X,Y)$ , else player I wins. It is intended that at a time  $t$ , player I has complete information about all previous moves  $\bar{Y}(t-1)$  of his opponent, and player J has complete information about all previous moves  $\bar{X}t$  of his opponent. More rigorously this can be stated thus,

**DEFINITION 3.** A strategy for player I (for player J), in a game  $C(X,Y)$ , is a deterministic 1-shift operator  $X=B(Y)$  (deterministic 0-shift operator  $Y=A(X)$ ). If  $\langle B,A \rangle$  is a pair of such strategies, then the play  $\langle B,A \rangle$  produces the pair  $\langle X_0, Y_0 \rangle$  such that  $A(X_0) = Y_0$  and  $B(Y_0) = X_0$ . The strategy  $A$  (of player J) beats the strategy  $B$  (of player I) in case  $C(X_0, Y_0)$ . Otherwise  $B$  beats  $A$ . A winning strategy for either player is one which beats all strategies of the opponent.

That the play  $\langle B,A \rangle$  exists has been pointed out in the proof of Lemma 1. We leave it to the reader to verify.

LEMMA 2. An operator  $Y=A(X)$  ( $X=B(Y)$ ) is a winning strategy for player J (player I) in the game  $C(X,Y)$  if and only if it is a deterministic 0-shift (1-shift) solution of the condition C for  $Y$  ( $\sim C$  for  $X$ ).

Thus Lemma 1 asserts the intuitively obvious fact that in no game  $C$  can both players possess a winning strategy. Furthermore, the condition  $C(X,Y)$  is determined (Definition 1) just in case the game  $C$  is determined in the sense that one of the two players possesses a winning strategy.

If  $C(X,Y)$  is called a finite state game in case it is the  $\omega$ -behavior of a finite automata operator of form (5) with an output  $U$ , then Theorem 1 takes the following form.

THEOREM 1'. Every finite state game is determined. Moreover, the player who has a winning strategy in fact has one which can be executed by a finite automaton.

We leave it to the reader to make up a particular finite state game and to meditate about the sense in which such a game can actually be played. We also suggest that he review the results of section 4 in game terminology.

We would like to emphasize here that the second stronger part of Theorem 1' is critical for our solvability algorithm (section 4). This second part is also a new kind of result in game theory. More generally, the following type of game problems are naturally suggested by automata theory. Given a class of games  $G$ :

- 1) Can one effectively decide, for any  $C \in G$ , which player has a

winning strategy? 2) Just how simple winning strategies do exist for games in  $G$ ? For example, is there a recursive or even a finite automata winning strategy for  $CeG$ ? This general problem was considered in [17].

We suggest that the arithmetic hierarchy [11] provides more natural choices of  $G$  (in connection with the above questions), than does the classical Borel hierarchy considered in the literature [7,10,15]. To state a more concrete question we ask,

PROBLEM. For any  $\forall_3$ -game is there a winning strategy in the arithmetic hierarchy of operators? If yes, how high do they occur in the hierarchy?

Here  $\forall_3$  stands for the class of all  $C(X,Y)$  which are of the form  $(\forall x)(\exists y)(\forall z)B(X,Y,x,y,z)$ , whereby  $B$  is recursive. Note that  $\forall_3$  is contained in  $F_{\sigma\delta}$  of the Borel hierarchy over the product of the natural Cantor spaces of  $I$ -sequences and  $J$ -sequences (since  $B(X,Y,x,y,z)$  is open and closed for fixed  $x,y$  and  $z$ ). Hence  $\forall_3$  games are determined as a consequence of the following result of Davis [7].

(\*) All  $F_{\sigma\delta}$  games are determined.

It is easy to show, using the axiom of choice, that there is a  $C(X,Y)$  which is not determined [10]. However, it is not known whether all  $F_{\sigma\delta\sigma}$  or even all  $\forall_4$  games are determined.

For comparison with our stronger proof of the full Theorem 1!, we end this digression into game theory with a proof, using (\*), that all finite state games are determined. In fact Theorem 2 below is somewhat stronger.

Call  $C(X,Y)$  a continuous-sup-condition (recursive-sup-condition) if it is of the form,  $\sup Z \in U$  if  $Z = E(X,Y)$ , whereby  $E$  is a continuous operator (recursive operator). I.e.,

$$(8) \quad C(X,Y) \equiv (\exists Z)[(\forall t) Zt = \Phi(\bar{X}(\phi t), \bar{Y}(\phi t)) \wedge \sup Z \in U]$$

where  $\Phi$  and  $\phi$  are arbitrary (recursive) functions. Note that  $\omega$ -behaviors (i.e., finite state games) are recursive-sup.

LEMMA 3. Every continuous-sup-condition (recursive-sup-condition)  $C$  is in the Boolean algebra over  $F_\sigma$  (over  $\exists_2$ ).

PROOF. Assume  $C$  is given by (8), but drop the second argument  $Y$  to avoid notational complexity. Using the definition of  $\sup$  (6) it follows that,

$$C(X) \equiv \bigvee_{B \in U} [(\exists y)(\forall t)[y \leq t \supset \Phi(\bar{X}(\phi t)) \in B] \wedge \bigwedge_{s \in B} (\forall y)(\exists t)[y \leq t \wedge \Phi(\bar{X}(\phi t)) = s]].$$

Note that  $U$  and its members  $B$  are finite sets, so that  $C(X)$  is a Boolean combination of expressions of the form  $(\exists y)(\forall t) M(X,y,t)$ . The expressions  $M(X,y,t)$ , namely  $[y > t \vee \Phi(\bar{X}(\phi t)) \in B]$  or  $[y > t \vee \Phi(\bar{X}(\phi t)) \neq s]$  (for various values of  $B$  and  $s$ ), denote clopen sets for fixed  $y$  and  $t$  (recursive relations in case  $\Phi$  and  $\phi$  are recursive). This is true because  $M(X,y,t)$  implies  $M(X^*,y,t)$  whenever  $\bar{X}^*(\phi(t)) = \bar{X}(\phi(t))$ . Consequently each  $(\exists y)(\forall t) M(X,y,t)$  denotes an  $F_\sigma$  (an  $\exists_2$ ) so that  $C$  is a Boolean combination of  $F_\sigma$ 's (of  $\exists_2$ 's). Q.E.D.

THEOREM 2. Every continuous-sup-game (recursive-sup-game)  $C(X,Y)$  is determined.

The proof is obvious from (\*) and Lemma 3. We have not investigated whether Davis' proof of (\*) can be analyzed to yield further information in case one assumes  $C(X,Y)$  to be recursive-sup (or even an  $\omega$ -behavior). At any rate, if  $C(X,Y)$  is an  $\omega$ -behavior our Theorem 1' strengthens Theorem 2.

It seems unlikely that there is a presentation for recursive-sup-conditions which admits a method for deciding which of the players has a winning strategy. Note that our Theorem 6 states the existence for sequential conditions.

PROBLEM. Is it true that for every recursive-sup-game either of the players has a winning strategy which is arithmetical? If yes, how high does it occur?

#### 4. A SOLVABILITY-SYNTHESIS ALGORITHM FOR SEQUENTIAL CALCULUS

Our concern here is not so much to determine solutions for particular conditions. We rather ask for algorithms which for a class CL of conditions determine solvability questions with respect to a class OP of operators. Such algorithms are discussed in the literature [2,5,6,8,9,18,19]. We will restate some known results and show what our basic Theorem 1 provides.

Let CL be an interpreted formalism (called the condition language) containing formulas  $C(X,Y)$  denoting relations between  $\omega$ -sequences. Let OP be a class of operators. A solvability algorithm for CL with respect to OP is an effective procedure

which applies to any  $C(X,Y) \in CL$  and tells whether or not  $C$  admits a solution  $A \in OP$  for  $Y$ . In case the members of  $OP$  are finitely presentable (as is an FAO by a finite automaton and a RDO by a Turing machine computing  $\Phi$ ), one may ask for a partial synthesis algorithm which for any  $C(X,Y) \in CL$  constructs a presentation of a solution  $A \in OP$ , if a solution exists, and a solution algorithm which, given a  $C(X,Y) \in CL$  and a presentation of some  $A \in OP$ , decides whether or not  $A$  solves  $C$  for  $Y$ .

In [4] sequential calculus (SC) is considered as a natural candidate for a condition language for FAO. SC is the monadic second-order theory of the successor function ' on natural numbers. That is SC is the interpreted formalism which includes the first order theory of  $\langle \omega, 0, ' \rangle$  and quantification over monadic predicate variables ranging over sets of natural numbers. Note that a subset  $X$  of  $\omega$  (i.e., predicate on  $\omega$ ) may also be interpreted as an  $\omega$ -sequence of members of  $\{T, F\}$ , and a finite sequence  $X = \langle X_1, \dots, X_k \rangle$  is an  $\omega$ -sequence of members of the set  $\{T, F\}^k$ . Thus, a formula  $C(X, Y)$  of SC with free predicate variables  $X = \langle X_1, \dots, X_h \rangle$  and  $Y = \langle Y_1, \dots, Y_k \rangle$  denotes a condition on  $\omega$ -sequences over  $I = \{T, F\}^h$  and  $J = \{T, F\}^k$ . Other finite  $I$  and  $J$  can be handled by coding their members as sequences of the truth-values  $T, F$ .

In [4] a method for deciding truth of sentences in SC was presented. Let  $Y = A(X)$  be a FAO given by (3). By appropriate coding of the automaton  $\langle K, H, L, W \rangle$  one can construct a formula  $F(X, Y) \in SC$  of form,

$$(\exists z_1 \dots z_n). z_1 0 \equiv H_1(0) \wedge \dots \wedge z_n 0 \equiv H_n(0) \wedge (\forall t)[z_1 t' \equiv L_1(t) \wedge \dots \\ \wedge z_n t' \equiv L_n(t')] \wedge (\forall t)[Y_1 t \equiv W_1(t) \wedge \dots \wedge Y_k t \equiv W_k(t)]$$

(whereby the  $H, L, W$ 's are propositional formulas in the atomic parts  $x_1 0, \dots, x_n 0, y_1 0, \dots, y_k 0, z_1 0, \dots, z_n 0, x_1 t', \dots, x_n t', y_1 t', \dots, y_k t', z_1 t, \dots, z_n t$ ), such that  $F(X, Y)$  means  $Y = A(X)$ . The assertion,  $A$  solves  $C(X, Y) \in SC$  for  $Y$ , where  $A$  is a FAO can therefore be stated as a sentence of SC. Hence,

THEOREM 3. There is a solution algorithm and a partial synthesis algorithm for SC with respect to FAO.

A partial synthesis algorithm is available because all finite automata can be effectively enumerated, and one after the other checked as to whether it solves a proposed condition  $C(X, Y)$  stated in SC. For a very small fragment of SC a solvability algorithm was found [4] and improved by Wright. This result can be extended to cover conditions of SC of the form

$$(\text{predicate prefix on } Z). H[Z] \wedge (\forall t) L[Xt, Yt, Zt, Zt']$$

(unpublished). It is easy to see [4] that addition of an existential conjunct  $(\exists t) M[Zt]$  to such formulas yields all conditions  $C(X, Y)$  expressible in SC. However, even for very special formulas including both kinds of individual quantifiers the problem of finding a solvability algorithm was left open in [6], and seemed rather hopeless at that time. It is only by using McNaughton's fundamental lemma and our Theorem 1 that we are now able to give a solvability algorithm for all of SC.

The main definability result of [4] can be restated thus:  
 To every formula  $C(X,Y)$  of SC one can construct a transition system  $\langle S,K,L,U \rangle$  with output condition whose  $\omega$ -behavior is (the relation defined by)  $C$ . Thus by the fundamental lemma,

**THEOREM 4.** To every formula  $C(X,Y)$  of SC one can effectively construct a finite automaton with output  $\langle S,s_0,H,U \rangle$  whose  $\omega$ -behavior is (the relation defined by)  $C$ .

Conversely, every  $\omega$ -behavior can be defined in SC. In fact (7) with  $\sup Z$  replaced by its definition (6), up to coding, yields such a definition (as  $x \leq y$  is definable in SC by  $(\forall Z)[Zy \wedge (\forall t)[Zt' \supset Zt] \supset Zx]$ ). Also note that the fundamental lemma yields another proof of the critical lemma 9 of [4], which does not make use of Ramsey's Theorem.

Because of Theorem 4 we can extend Theorem 1 to,

**THEOREM 5.** Every condition  $C(X,Y)$  definable in SC is determined. In fact, either there is a 0-shift FAO which solves  $C$  for  $Y$  or else there is a 1-shift FAO which solves  $\sim C$  for  $X$ .

Because of lemma 1 we have,

**COROLLARY.** If  $C(X,Y)$  in SC has a deterministic solution for  $Y$  then it has a FAO solution for  $Y$ .

The corollary generalizes the statement: If  $C(Y)$  in SC holds for some  $Y$ , then it holds for ultimately periodic  $Y$ . Just note that a FAO solution of  $C(Y)$  for  $Y$  is an input free automaton.

THEOREM 6. There is an algorithm which for any  $C(X,Y)$  of SC,  
 1) decides whether  $C(X,Y)$  is deterministically solvable for Y, ..  
 2) produces a 0-shift FAO solution of  $C(X,Y)$  for Y (if C  
 is deterministically solvable for Y), 3) produces a 1-shift  
 FAO solution of  $\sim C(X,Y)$  for X (if C is not deterministically  
 solvable for Y).

PROOF. Algorithm 1: Systematically list all 0-shift FAO  
 $Y=A(X)$  and all 1-shift FAO  $X=B(Y)$ . Check whether A solves C  
 for Y or B solves  $\sim C$  for X using the algorithm of Theorem 3.  
 By Theorem 5, eventually a solution of C for Y or a solution of  
 $\sim C$  for X will be found.

Algorithm 2: Use the algorithm of Theorem 4 to put  $C(X,Y)$   
 in finite state form. Then use the method described in section 5.

Note that there is a solvability algorithm for SC with  
 respect to DO, which is also a solvability algorithm for SC with  
 respect to FAO (Theorem 6). However, while there is a  
 solution algorithm with respect to FAO (Theorem 3), there is  
 no solution algorithm for SC with respect to RDO.  
 For example, let  $C(X,Y)$  be  $(\exists y)(\forall z)[y < z \supset \sim Yz]$ . Let  
 $Y=A_Q(X)$  be the RDO defined by

$$Yt = \begin{cases} T & \text{if } t \in Q \\ F & \text{if } t \notin Q \end{cases}$$

whereby Q is a recursive set.  $A_Q$  solves C for Y if and only  
 if Q is finite. Hence a solution algorithm for SC with respect  
 to RDO would, given an index for Q, decide whether it is finite.  
 It is well known that such a method does not exist.

We have not seriously investigated whether the algorithms of

Theorems 3 and 6 can be improved to a point of usefulness in the design of sequential circuits. As they include conversion of propositional formulas into normal form, it seems that presently available computing equipment could not carry a significant part of out algorithms. Nevertheless, our solution automata of section 5, like the construction of [14], provide examples of strictly finite devices which accomplish surprisingly intricate tasks.

The fundamental lemma can be extended to  $\alpha$ -behaviors, for any countable ordinal  $\alpha$ . This leads to a decision method for the monadic second order theory of  $\langle \alpha, . \rangle$  (see [1]). We hope to present elsewhere a corresponding extension of Theorem 6 from  $\omega$  to any countable ordinal  $\alpha$ .

$C(X,Y)$  admits an  $h$ -shift solution for  $Y$ , if and only if,  $C_h(X,Y) : (\exists Z). C(Z,Y) \wedge (\forall t) Zt = X(t+h)$  has a 0-shift solution for  $Y$ . Thus, for any fixed  $h$ , Theorem 6 yields a solvability algorithm for SC with respect to  $h$ -shift DO's and FAO's. Note that any  $(h+1)$ -shift recursion is also an  $h$ -shift recursion. This suggests,

Problem: Can one algorithmically determine whether or not for a condition  $C(X,Y)$  stated in SC there exists an  $h$  such that  $C$  admits an  $h$ -shift, but no  $(h+1)$ -shift solution for  $Y$ ?

## 5. SOLVING FINITE STATE CONDITIONS

We will present here our main proof, that of Theorem 1. Therefore, throughout this section  $C(X,Y)$  will be the  $\omega$ -behavior, with respect to  $U$ , of the FAO given by

$$(9) \quad \begin{aligned} ZO &= s_0 \\ Zt' &= H[Xt, Yt, Zt] \end{aligned}$$

Let  $I, J, S$  be the finite sets of states of  $X, Y, Z$  respectively, so that  $U$  is a class of subsets of  $S$ . We recall that  $C(X, Y)$  stands for  $\sup_{Z \in U} Z$ , whereby  $Z$  is given by (9).

Our proof is outlined as follows. In section (a) we will construct a subset  $R_\ell[ ]$  of the set of states  $S$ , such that if  $s_0 \in R_\ell[ ]$  then  $C(X, Y)$  is solvable for  $Y$  by a 0-shift FAO, and if  $s_0 \notin R_\ell[ ]$  then  $\sim C(X, Y)$  is solvable for  $X$  by a 1-shift FAO. Thus,  $s_0 \in R_\ell[ ]$  is the condition of solvability of  $C(X, Y)$  for  $Y$ . The case  $s_0 \in R_\ell[ ]$  is treated in section (b), where we will present a 0-shift FAO  $Y=A(X)$  which solves  $C$  for  $Y$ . The case  $s_0 \notin R_\ell[ ]$  is treated in section (c), where a 1-shift FAO  $X=B(Y)$  is presented which solves  $\sim C$  for  $X$ .

(a) Definition of  $R_\ell[ ]$ . For each  $A \in U$  choose a cyclic permutation of its members. For simplicity of notation we denote the value of this permutation at  $s \in A$  by  $A(s)$ . The crucial construction is that of the sets  $R_k[A_1, s_1, \dots, A_n, s_n]$ ,  $P_k[A_1, s_1, \dots, A_n, s_n]$ , and  $Q_k[A_1, s_1, \dots, A_n, s_n]$ , whereby  $n \geq 0$ ,  $A_1 \supset \dots \supset A_n$  range over strictly decreasing chains in  $U$  and  $s_1, \dots, s_n$  range over members of  $A_1, \dots, A_n$ , respectively. These sets are defined simultaneously by the following induction on  $k = 0, 1, 2, \dots$ .

$$\begin{aligned}
s \in R_0[A_1, s_1, \dots, A_n, s_n] &\equiv \text{false} \\
s \in P_k[A_1, s_1, \dots, A_n, s_n] &\equiv s \in R_k[\ ] \vee s \in A_1 \cap R_k \vee \dots \\
&\vee s \in A_n \cap R_k[A_1, s_1, \dots, A_n, s_n] \\
(10) \quad s \in Q_k[A_1, s_1, \dots, A_n, s_n] &\equiv \bigvee_B B \in U \wedge s \in B \subseteq A_n \wedge \\
&\bigwedge_{u \in B} u \in R_k[A_1, s_1, \dots, A_n, s_n, B, B(u)] \\
s \in R_{k+1}[A_1, s_1, \dots, A_n, s_n] &\equiv \bigwedge_{x \in I} \bigvee_{y \in J} H[x, y, s] \in \{s_1, \dots, s_n\} \cup \\
&P_k[A_1, s_1, \dots, A_n, s_n] \cup Q_k[A_1, s_1, \dots, A_n, s_n]
\end{aligned}$$

Note that  $n$  is bounded by the length of maximal chains in  $U$ .

If  $n=0$  we use the notations  $R_k[\ ]$ ,  $P_k[\ ]$ ,  $Q_k[\ ]$ .

Caution! In interpreting (10) for the case  $n=0$  the occurrence of  $A_n$  (in the expression  $s \in B \subseteq A_n$ ) is to be suppressed. A similar remark goes for all future occurrences of  $A_0$ .

By induction on  $k$ , one easily shows that  $R_k[v] \subseteq R_{k+1}[v]$ ,  $P_k[v] \subseteq P_{k+1}[v]$ ,  $Q_k[v] \subseteq Q_{k+1}[v]$ , for all arguments  $v = [A_1, s_1, \dots, A_n, s_n]$ . Because all  $R_k[v]$ ,  $P_k[v]$  and  $Q_k[v]$  are subsets of the finite set  $S$ , and there are but a finite number of  $v$ 's, it follows that there is a number  $k$  such that, for all  $v$ ,  $R_k[v] = R_{k+1}[v]$ ,  $P_k[v] = P_{k+1}[v]$  and  $Q_k[v] = Q_{k+1}[v]$ . Accordingly we define  $\ell$ ,

(11)  $\ell$  is the first number such that,  $R_{\ell-1}[v] = R_\ell[v]$ ,  $P_{\ell-1}[v] = P_\ell[v]$ , and  $Q_{\ell-1}[v] = Q_\ell[v]$ , for all  $v = [A_1, s_1, \dots, A_n, s_n]$ ,  $A_1 \supset \dots \supset A_n$ ,  $n \geq 0$ .

From (10) and (11) we obtain

$$\begin{aligned}
 s \notin R_\ell[A_1, s_1, \dots, A_n, s_n] &\equiv \bigvee_{x \in I} \bigwedge_{y \in J} H[x, y, s] \notin \{s_1, \dots, s_n\} \cup \\
 &\quad P_\ell[A_1, s_1, \dots, A_n, s_n] \cup Q_\ell[A_1, s_1, \dots, A_n, s_n] \\
 (12) \quad s \notin Q_\ell[A_1, s_1, \dots, A_n, s_n] &\equiv \bigwedge_B [B \in U \wedge s \in B \in A_n] \supset \\
 &\quad \bigvee_{u \in B} u \notin R_\ell[A_1, s_1, \dots, A_n, s_n, B, B(u)] \\
 s \notin P_\ell[A_1, s_1, \dots, A_n, s_n] &\equiv s \notin R_\ell[\ ] \wedge s \notin A_1 \cap R_1[A_1, s_1] \wedge \dots \\
 &\quad \wedge s \notin A_n \cap R_\ell[A_1, s_1, \dots, A_n, s_n]
 \end{aligned}$$

(b) The case  $s_0 \in R_\ell[\ ]$ : Choose a linear order of the members of  $J$  and  $U$ . An expression  $(\mu y) E(y)$  denotes the first member  $y$  of  $J$ , in the chosen order, which satisfies  $E(y)$ , if it exists. We will now display a 0-shift FAO  $Y=A(X)$ , and prove that it solves  $C(X, Y)$  for  $Y$ .

In the sequel  $X, Y, Z, k$  denote  $\omega$ -sequences over the sets  $I, J, S, \{0, \dots, \ell\}$ , respectively.  $V$  denotes  $\omega$ -sequences of elements of form  $[A_1, s_1, h_1, \dots, A_n, s_n, h_n]$ , whereby  $n \geq 0$ ,  $A_1 \supset \dots \supset A_n$  is a chain of members of  $U$ ,  $s_1 \in A_1, \dots, s_n \in A_n$  and  $\ell > h_1 > \dots > h_n$ . Consider the following formulas,

$$Z_0 = s_0, \quad V_0 = [ ], \quad h_0 = \ell$$

$$\text{if } V_t = [A_1, s_1, h_1, \dots, A_n, s_n, h_n] \text{ let}$$

$$Y_t = (\mu y). H[X_t, y, Z_t] \in \{s_1, \dots, s_n\} \cup$$

$$P_{kt-1}[A_1, s_1, \dots, A_n, s_n] \cup Q_{kt-1}[A_1, s_1, \dots, A_n, s_n]$$

$$Z_{t'} = H[X_t, Y_t, Z_t]$$

( $\alpha$ ) if  $Z_{t'} \in \{s_1, \dots, s_n\}$ , let  $i$  be the first such that

$$Z_{t'} = s_i. \text{ Then}$$

$$V_{t'} = [A_1, s_1, h_1, \dots, A_i, A_i(s_i), h_i]$$

$$(13) \quad kt' = h_i$$

( $\beta$ ) if  $Z_{t'} \in P_{kt-1}[A_1, s_1, \dots, A_n, s_n]$  but not ( $\alpha$ ), let  $j$

be the first such that  $Z_{t'} \in A_j \cap R_{kt-1}[A_1, s_1, \dots, A_j, s_j]$

( $Z_{t'} \in R_{kt-1}[ ]$  if  $j=0$ ). Then,

$$V_{t'} = [A_1, s_1, h_1, \dots, A_j, s_j, h_j]$$

$$kt' = kt - 1$$

( $\gamma$ ) if  $Z_{t'} \in Q_{kt-1}[A_1, s_1, \dots, A_n, s_n]$  but neither ( $\alpha$ ) nor ( $\beta$ ),

let  $B$  be the first in the chosen order of  $U$  such

that,  $Z_{t'} \in B \subseteq A_n$  and  $\bigwedge_{u,v \in B} u \in R_{kt-1}[A_1, s_1, \dots, A_n, s_n, B, v]$ .

Then

$$V_{t'} = [A_1, s_1, h_1, \dots, A_n, s_n, h_n, B, B(Z_{t'}), kt-1]$$

$$kt' = kt-1$$

and the formulas,

$$\begin{aligned}
& Z_t \in R_{kt}[A_1, s_1, \dots, A_n, s_n], \quad Z_t \in A_n \quad (\text{if } n \neq 0) \\
(14) \quad & A_1 \supset \dots \supset A_n, \quad s_i \in A_i \in U, \quad \ell > h_1 > \dots > h_n > kt > 0 \\
& \bigwedge_{u, v \in A_i} u \in R_{h_i}[A_1, s_1, \dots, A_i, v], \quad \text{if } Vt = [A_1, s_1, h_1, \dots, A_n, s_n, h_n]
\end{aligned}$$

Because we are dealing with the case  $s_0 \in R_\ell[ ]$ , the values  $Z_0, V_0, k_0$  given by (13) clearly satisfy (14). Assume inductively that (14) holds for  $t$ , and  $X_t$  is arbitrary. Using (10) it follows that there is a  $y \in J$  such that  $H[X_t, y, Z_t] \in \{s_1, \dots, s_n\} \cup P_{kt-1}[A_1, s_1, \dots, A_n, s_n] \cup Q_{kt-1}[A_1, s_1, \dots, A_n, s_n]$ , and therefore  $Y_t$  exists as described by (13), and so do  $Z_t', V_t', k_t'$ , in all cases  $(\alpha), (\beta), (\gamma)$ . Furthermore, one easily checks that these values  $Z_t', V_t', k_t'$  satisfy (14) with  $t$  replaced by  $t'$ . Thus, the formulas (13) constitute a recursive definition of  $Y, Z, V, k$  from  $X$ , and furthermore, (13) implies (14).

Let  $Y=A(X)$  be the operator from  $I$ -sequences to  $J$ -sequences, given by (13). Then  $A$  clearly is deterministic and recursive. Furthermore, because of (14), the auxiliaries  $Z, V, k$  in the recursion (13) are finite valued. In fact it is easy to modify (13) so that it is of form (3). Therefore,  $A$  is a 0-shift FAO. It remains to show that  $A$  solves  $C$  for  $Y$ , i.e., that (1) holds.

Note that a copy of (9) is built into the definition (13) of  $A$ . As a consequence the assertion (1) is tantamount to the assertion: For any  $X, Y, Z, V, k$ , (13) implies  $\sup Z \in U$ . The remainder of section (b) constitutes a proof of this.

Assume that (13), and therefore (14), holds for  $X, Y, Z, V, k$ . From (13) one easily sees that  $Vt_1 = [ ]$  and  $t_1 < t_2$  implies

$kt_1 > kt_2$ . Therefore, by (14), there can be but finitely many  $t$  such that  $Vt = [ ]$ . Accordingly there is a  $t_1$  such that,  $Vt \neq [ ]$  for all  $t \geq t_1$ , i.e., if  $t \geq t_1$  then  $Vt$  is of form  $[A_1, s_1, h_1, \dots, A_n, s_n, h_n]$  with level  $n \geq 1$ .

As the level  $n$  of  $Vt$  is bounded by the lengths of chains in  $U$  (see (14)), some level  $n \geq 1$  must occur infinitely often. Let  $m$  be the smallest of these. Then,  $m \geq 1$  and there is a  $t_2$  such that for all  $t \geq t_2$  the level of  $Vt$  is  $\geq m$ . Thus we have,

If  $t \geq t_2$  then  $Vt = [A_1, s_1, k_1, \dots, A_m, s_m, k_m, \dots, A_n, s_n, k_n]$   
 (15) thereby  $n \geq m$ . Furthermore,  $n = m$  occurs for infinitely many times  $t$ .

It follows from (15) that for  $t' > t_2$  only the cases  $(\alpha) i \geq m$ ,  $(\beta) j \geq m$ , and  $(\gamma) n \geq m$  of (13) can occur. Consequently, for  $t \geq t_2$  the entry  $A_m$  (and all previous entries) in  $Vt$  remains constant. By (14) it follows that  $Zt \in A_m$  for  $t \geq t_2$ ,  $A_m \in U$ . Thus  $\sup Z \subseteq A_m \subseteq U$ .

Suppose the case  $(\alpha) i = m$  occurred for only finitely many  $t$ . Then there would be a  $t_3 > t_2$  such that for  $t \geq t_3$  only the cases  $(\alpha) i > m$ ,  $(\beta) j \geq m$ ,  $(\gamma) n \geq m$  could occur. Inspection of (13,14) shows that then also the case  $(\beta) j = m$  could occur only for finitely many  $t \geq t_3$  (because each application of 0 or more steps  $(\gamma) n \geq m$ ,  $(\alpha) i > m$ ,  $(\beta) j > m$  followed by  $(\beta) j = m$  lowers the value of  $k$ ). Thus, both cases  $(\alpha) i = m$  and  $(\beta) j = m$  would occur only finitely often. This contradicts the second part of (5). Therefore the case  $(\alpha) i = m$  must occur infinitely often.

Let  $t_3 < t_4 < t_5 < \dots$  be the infinitely many consecutive places  $t > t_2$  where  $(\alpha) i = m$  is used. It clearly follows that  $Zt_4 = A_m(Zt_3)$ ,  $Zt_5 = A_m(Zt_4)$ ,  $Zt_6 = A_m(Zt_5), \dots$ . Because  $s \rightarrow A_m(s)$  was chosen to be a cyclic permutation of  $A_m$ , it follows that  $Z$  will keep taking any value in  $A_m$ . Thus,  $\sup Z \supseteq A_m$ . Together with a former result, this yields  $\sup Z = A_m \in U$ . Q. E. D.

(c) The case  $s_0 \notin R_\ell[\ ]$ : Choose a linear order of  $I$ . The expression  $(\mu x)E(x)$  denotes the first  $x$  in  $I$  such that  $E(x)$ , if it exists. We will now display a 1-shift FAO  $X=B(Y)$ , and prove that it solves  $\sim C(X,Y)$  for  $X$ .

In the sequel  $X, Y, Z$  denote  $\omega$ -sequences over the sets  $I, J, S$ .  $V$  denotes  $\omega$ -sequences over elements of form  $[A_1, s_1, \dots, A_n, s_n]$ , whereby  $A_1 \supset \dots \supset A_n$  is a chain of members of  $U$  and  $s_1 \in A_1, \dots, s_n \in A_n$ .  $W$  denotes  $\omega$ -sequences of chains of subsets of  $S$ . Consider the following formulas,

$$Z_0 = s_0 \quad W_0 = \{\{s_0\}\} \quad V_0 = [ \ ]$$

$$\text{if } Vt = [A_1, s_1, \dots, A_n, s_n] \text{ and } A_{n+1} = \Lambda \text{ let}$$

$$Xt = (\mu x) \bigwedge_{y \in J} H[x, y, Zt] \notin \{s_1, \dots, s_n\} \cup \ell[A_1, s_1, \dots, A_n, s_n] \cup$$

$$Q_\ell[A_1, s_1, \dots, A_n, s_n]$$

$$Zt' = H[Xt, Yt, Zt]$$

$$Wt' = \{B \cup \{Zt'\} ; B \in Wt \vee B = \Lambda\}$$

(16)

$$(\alpha) \text{ If } \bigvee_B B \in U \cap Wt' \wedge \bigvee_{0 \leq i \leq n} [A_i \supset B \supset A_{i+1} \wedge Zt' \notin R_\ell[A_1, s_1, \dots, A_i, s_i, B, B(Zt')]], \text{ let } B \text{ be the largest such. Then,}$$

$$Vt' = [A_1, s_1, \dots, A_i, s_i, B, B(Zt')]$$

( $\beta$ ) If not ( $\alpha$ ), let  $i$  be such that  $Zt' \in A_i$ ,  $Zt' \notin A_{i+1}$ .

$$Vt' = [A_1, s_1, \dots, A_i, s_i]$$

and the formulas,

if  $Vt = [A_1, s_1, \dots, A_n, s_n]$  then,

$$Zt \notin R[A_1, s_1, \dots, A_n, s_n]. \quad A_1 \supset \dots \supset A_n \text{ all in } U \cap Wt$$

$$Zt \in A_n \text{ (if } n \neq 0) \quad , \quad s \in A_1, \dots, s_n \in A_n$$

$Wt$  is a chain of subsets of  $S$

Because we are dealing with the case  $s_0 \notin R_\ell[ ]$ , the values  $Z_0, P_0, V_0$  given by (16) satisfy (17) for  $t = 0$ . Assume inductively that (17) holds for  $t$  and  $Yt$  is any member of  $J$ . By (12) it follows that  $Xt, Zt', Wt'$  as prescribed by (16) exists. Furthermore,  $Wt'$  is still a chain of subsets of  $S$ , and  $Zt' \notin P_\ell[A_1, s_1, \dots, A_n, s_n]$ . By (12) it therefore follows that, in cases ( $\beta$ ), (17) holds for  $t$  replaced by  $t'$ . The same can easily be checked in case  $Vt'$  is calculated by ( $\alpha$ ). The preceding argument shows that (16) constitutes a recursive definition of  $Z, W, V, X$  from  $Y$ , and that (16) implies (17).

Let  $X=B(Y)$  be the operator from  $I$ -sequences to  $J$ -sequences, given by (16). Then  $B$  clearly is a 1-shift deterministic operator. Furthermore, the auxiliaries  $Z, W, V$  take values in finite sets (see (17)). In fact, the recursion (16) is easily modified to the

form (3'). Thus,  $X=B(Y)$  is a 1-shift FAO. To terminate the proof of Theorem 1, it remains to be shown that  $B$  solves  $\sim C(X,Y)$  for  $X$ , i.e., that  $X=B(Y)$  and (9) imply  $\sup Z \notin U$ .

Note that the recursion (9) is built into the definition (16) of  $X=B(Y)$ . As a consequence, ' $B$  solves  $C(X,Y)$  for  $X$ ' is tantamount to the assertion: (16) implies  $\sup Z \notin U$ . The remainder of this section constitutes a proof of this, in the form: (16) and  $\sup Z \in U$  yields a contradiction.

For the sequel assume that (16), and therefore (17), holds for  $X,Y,Z,W,V$ . Furthermore, assume  $\sup Z = D \in U$ . It follows that there is a  $t_1$  such that

$$(18) \quad \begin{aligned} t \geq t_1 &\supset Zt \in D \\ u \in D &\supset (\exists t)[t \geq a \wedge Zt=u], \text{ for any time } a. \end{aligned}$$

From (16) one clearly sees that the chain  $Wt$  consists of all sets  $\{Z_0, \dots, Zt\}, \{Z_1, \dots, Zt\}, \dots, \{Z(t-1), Zt\}, \{Zt\}$ . It follows from (18), and  $D \in U$  that there is a time  $t_2 \geq t_1$ , such that

$$(19) \quad t \geq t_2 \supset D \in UNWt$$

Let  $Vt = [A_1, s_1, \dots, A_n, s_n]$ . From (16),  $Zt' \notin Q_\ell[A_1, s_1, \dots, A_n, s_n]$ . Because of (12) and  $B \in Wt' \supset Zt' \in B$  this yields,

$$[B \in UNWt' \wedge A_n \supset B] \supset \bigvee_{u \in B} u \notin R_\ell[A_1, s_1, \dots, A_n, s_n, B, B(u)]$$

This and (19) yield,

$$[t \geq t_2 \wedge A_n \supset D] \supset \bigvee_{u \in D} u \notin R_\ell[A_1, s_1, \dots, A_n, s_n, D, D(u)]$$

Because of (18) this yields,

$$(20) \quad [t \geq t_2 \wedge \forall t=[A_1, s_1, \dots, A_n, s_n] \wedge A_n \supset D] \supset \\ (\exists a)[a \geq t \wedge \exists a' \notin R_\ell[A_1, s_1, \dots, A_n, s_n, D, D(Za')]]$$

Define the quasi-order  $\rightarrow$  on chains  $A_1 \supset \dots \supset A_p$  ( $p \geq 0$ )  
cf members of  $U$  by:

$$[B_1, \dots, B_q] \rightarrow [A_1, \dots, A_p] \equiv \bigvee_{1 \leq i \leq q, p} [\bigwedge_{1 \leq j < i} A_j = B_j \wedge A_i \supset B_i] \\ [\bigwedge_{1 \leq j \leq q} A_j = B_j \wedge p > q]$$

By the principal part of the chain  $A_1 \supset \dots \supset A_n$  (of  $[A_1, s_1, \dots, A_n, s_n]$ )  
we mean the chain  $A_1 \supset \dots \supset A_p$  (the sequence  $[A_1, s_1, \dots, A_p, s_p]$ )  
whereby  $p$  is the largest  $i$  such that  $A_i \supseteq D$ , or  $p = 0$  if  
there is no such  $i$ . Note that  $A_p \supset D \supset A_{p+1}$  if  $i \leq p < n \neq 0$ .  
 $D \supset A_1$  if  $p=1$ ,  $p=0$  if  $n=0$ .

Let  $Vt=[A_1, s_1, \dots, A_n, s_n]$ , let  $[A_1, s_1, \dots, A_p, s_p]$  be the  
principal part of  $Vt$ . Inspection of (16) shows that the  
principal part of  $Vt'$  will be equal or larger (in the sense of  $\rightarrow$ ),  
except if  $(\beta)_{i < p}$  comes to use. If  $t \geq t_2$ , so that by (18),  
 $Zt' \in D \supseteq A_p$ ,  $(\beta)_{i < p}$  cannot come to use. Therefore, for  $t \geq t_2$   
the principal part of  $Vt$  either stays equal or increases. Because  
 $\rightarrow$  is a quasi-order on a finite set, there must be a  $t_3 \geq t_2$   
such that the principal part of  $Vt$  remains constant from  $t_3$  on.  
I.e., there are  $m \geq 0$ ,  $\bar{A}_1, \bar{s}_1, \dots, \bar{A}_m, \bar{s}_m$  such that  $\bar{A}_m \supseteq D$  and,

$$(21) \quad \text{if } t \geq t_3 \text{ then } Vt \text{ is of form } [\bar{A}_1, \bar{s}_1, \dots, \bar{A}_m, \bar{s}_m, \dots, A_n, s_n] \\ \text{whereby } n = m \text{ or } D \supset A_{m+1} \supset \dots \supset A_n.$$

Assume that, for all  $t \geq t_3$ ,  $\forall t$  were of form  $[\bar{A}_1, \bar{s}_1, \dots, \bar{A}_m, \bar{s}_m, A_{m+1}(t), s_{m+1}(t), \dots]$ . By (16), it follows that  $A_{m+1}(t') \supseteq A_{m+1}(t)$ , for all  $t \geq t_3$ . Thus, there would have to be a  $c \geq t_3$  such that  $A_{m+1}(t)$  remained constant, say  $= A$ , from  $c$  on. By (21)  $D \supset A$ , so that by (18) there would exist a  $d \geq c$ ,  $Zd' \notin A$ . But  $Vd = [\bar{A}_1, \bar{s}_1, \dots, \bar{A}_m, \bar{s}_m, A, \dots]$ , so that the case  $(\beta)_{i=m}$  of (16) would come to play. As a result,  $Vd' = [\bar{A}_1, \bar{s}_1, \dots, \bar{A}_m, s_m]$ . This is contradictory to the assumption, so that there must be a  $t_4 \geq t_3$  such that,

$$(22) \quad \forall t_4 = [\bar{A}_1, \bar{s}_1, \dots, \bar{A}_m, \bar{s}_m]$$

Assume  $\bar{A}_m \supset D$ , or  $m = 0$ . By (20) and (22) there would be an  $a \geq t_4$  such that  $Za' \notin R_\ell[\bar{A}_1, \bar{s}_1, \dots, \bar{A}_m, \bar{s}_m, D, D(Za')]$ . By (21),  $Va = [\bar{A}_1, s_1, \dots, \bar{A}_m, \bar{s}_m]$ , or  $Va = [\bar{A}_1, s_1, \dots, \bar{A}_m, \bar{s}_m, A, \dots]$  and  $D \supset A$ . By (19),  $D \in U \cap Wa'$ . Thus,  $D$  is a possible value for  $B$  in  $(\alpha)$  of (16). Therefore,  $(\alpha)$  for some  $B \supseteq D$  would come to use for calculating  $Va'$ . The result would be an entry  $B \neq \bar{A}_1, \dots, \bar{A}_m, B \supseteq D$  in  $Va'$ . This contradicts (21). Therefore,

$$(23) \quad m \geq 1 \quad \bar{A}_m = D.$$

From (16) it clearly follows that  $Zt' \neq s_m$  if  $\forall t' = [A_1, s_1, \dots, A_m, s_m, \dots]$ . Therefore, by (21) and (17),  $Zt' \neq \bar{s}_m \in \bar{A}_m$  for any  $t \geq t_3$ . It follows that  $\bar{A}_m$  can not be  $\sup Z$ , i.e.,  $\bar{A}_m \neq D$ . Together with (23) this yields the contradiction, ending the proof of Theorem 1.

The reader will easily find various modifications of our recursions (13) which also define DO's which solve  $C(X,Y)$  for  $Y$  in case  $s_0 \in R_\ell[ ]$ . For example, such a recursion may keep  $Zt' \in R_\ell[ ]$  up to a fixed time  $h$  and from there on act like (13). More generally, the time  $h$ , at which the forcing of  $\sup Z$  into  $U$  is actually started, may be made to depend on the input  $X$ , and may be set and reset, deterministically depending on  $X$ . We have not investigated the following question.

Problem: Modify the recursions (13) to a schema with parameters which, by proper additional specifications for the parameters, will yield any given deterministic operator which solves  $C(X;Y)$  for  $Y$ . Do the same for (16) and solutions of  $C(X,Y)$  for  $X$ .

To accomplish this it might be necessary to make (more basic) changes in the definition (10) of the sets  $R_k[A_1, s_1, \dots, A_n, s_n]$ , which would make our proofs less intricate.
