Abstract. We consider lexicographic bi-objective problems on Markov Decision Processes (MDPs), where we optimize one objective while guaranteeing optimality of another. We propose a two-stage technique for solving such problems when the objectives are related (in a way that we formalize). We instantiate our technique for two natural pairs of objectives: minimizing the (conditional) expected number of steps to a target while guaranteeing the optimal probability of reaching it; and maximizing the (conditional) expected average reward while guaranteeing an optimal probability of staying safe (w.r.t. some safe set of states). For the first combination of objectives, which covers the classical frozen lake environment from reinforcement learning, we also report on experiments performed using a prototype implementation of our algorithm and compare it with what can be obtained from state-of-the-art probabilistic model checkers solving optimal reachability.

Keywords: Markov decision processes · Multi-objective · Synthesis.

1 Introduction

Probabilistic model-checkers, such as STORM [14] or PRISM [15], have been developed to solve the model-checking problem for logics like PCTL and models like Markov decision processes. These tools can be used to compute strategies (or schedulers) that maximize the probability of, for instance, reaching a set of states. As a concrete example, they can be used to solve the Frozen Lake problem shown in Figure 1, where a robot must navigate from an initial point to a target while avoiding holes in the ice. The ground is frozen and so the movements of the robot are subject to stochastic dynamics. While model-checkers provide optimal strategies for the probability of reaching the target, those strategies may not be efficient in terms of the expected number of steps required to reach it. For instance, the strategy returned by STORM for the grid given in Fig. 1 requires on average 345 steps to reach the target, while there are other strategies that are optimal for reachability that can reach the target in just 34 steps on average.

⁴ University of Antwerp – Flanders Make, Antwerp, Belgium

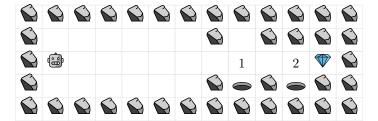

Fig. 1. In the game of Frozen Lake, a robot moves in a slippery grid. It has to reach the target (the gem) while avoiding holes in the grid. The robot can no longer move once in a hole. Part of the grid contains walls and the robot cannot move into them. The frozen surface of the lake being slippery, when the robot tries to move by picking a cardinal direction, the next state is determined stochastically over adjacent directions. For example, trying to move right would result on the robot going to the cell on the right with probability 0.8 but going up or down with probability 0.1 for each.

Indeed, a strategy can be optimal in terms of the probability to reach the target while (seemingly) behaving like a random walk on the grid (on portions without holes in particular). In the worst case, one could expect to reach the target after exponentially many steps (even on grids where there is a short and direct path to target), which can be considered useless for practical purposes.⁵ Therefore, in this context, we aim to not only maximize the probability of reaching the target, but also minimize the expected number of steps required to reach it, which is thus a multi-objective problem. Unfortunately, multi-objective optimization is not yet standard for probabilistic model checkers and most of them support it only for specific combinations of some objectives. For instance, Storm can solve the optimal reachability problem and compute the minimal expected cost to target, but only for target sets that can be reached with probability one. The latter is not usually the case in the Frozen Lake problem: the robot may need to walk next to a hole, and risk falling into it, in order to reach the target. In this paper, we demonstrate how to address the problems we have identified with the Frozen Lake example by leveraging the algorithms implemented in Storm.

We identify a family of bi-objective optimization problems that can be solved in two steps using readily available model-checking tools. This family of problems is formalized as follows. Let \mathcal{M} be an MDP and $\Sigma(\mathcal{M})$ the set of all strategies for it. We study reward functions that map strategies $\sigma \in \Sigma(\mathcal{M})$ to real numbers via the induced MDP \mathcal{M}_{σ} . Concretely, let $f, g : \Sigma(\mathcal{M}) \to \mathbb{R}$. We say a strategy

⁵ In particular, the strategy could be used as a component of some larger approach dealing with a more challenging problem too difficult for exact methods. In these cases, such as [6], one frequently relies on machine-learning techniques (e.g. Monte-Carlo methods or reinforcement learning) that run simulations for a fixed number of steps. Thus, a strategy that takes needlessly too many steps to reach a target will not help with learning practical and relevant strategies.

 $\sigma \in \Sigma(\mathcal{M})$ is f-optimal if $f(\sigma) = \sup_{\tau \in \Sigma(\mathcal{M})} f(\tau)$ and write Σ_f for the set of all f-optimal strategies.

There are multiple ways in which one can approach the problem of finding optimal strategies with respect to both f and g (see, e.g., [9] and references therein). In this work, we fix a lexicographic order on the functions. Formally, we want to compute a strategy σ such that the following holds.

$$\sigma \in \Sigma_f \text{ and } g(\sigma) = \sup_{\tau \in \Sigma_f} g(\tau)$$
 (1)

We propose a simple two-stage technique to compute σ such that Equation (1) is true. Intuitively, we first compute a finite representation of a set of strategies $\overline{\Sigma_f} \supseteq \Sigma_f$. Then, from $\overline{\Sigma_f}$, we construct a second MDP \mathcal{M}' such that all f-optimal strategies in \mathcal{M} are preserved, i.e. $\overline{\Sigma_f} \equiv \Sigma(\mathcal{M}')$, and such that the g function can be lifted to \mathcal{M}' while preserving the values of strategies. Our technique then outputs a g-optimal strategy from \mathcal{M}' . This procedure is correct under the following assumptions: To begin, we require the existence of an overapproximation $\overline{\Sigma_f}$ of Σ_f with a finite and computable representation. Further, we ask for the over-approximation $\overline{\Sigma_f}$ to satisfy the following condition. For all strategies σ , if the following is true:

$$\sigma \in \overline{\Sigma_f} \text{ and } g(\sigma) = \sup_{\tau \in S} g(\tau)$$
 (2)

then $\sigma \in \Sigma_f$. Intuitively, this can be read as g being related to or biased towards f when $\Sigma_f \subset \overline{\Sigma_f}$. When $\Sigma_f = \overline{\Sigma_f}$, this can be seen as a formalization of the shielding [2] framework and similar works [10], where one computes an exact representation of the set of all optimal strategies for the first objective then solves for the second objective within that space. It is worth noting that under the assumptions mentioned above, this technique can be implemented easily using off-the-shelf tools that are capable of both optimizing g and obtain $\overline{\Sigma_f}$ separately.

Our contribution. In this paper, we instantiate the technique described above for two concrete cases of f and g. We prove that in both cases our technique gives a polynomial-time solution for the problem. First, we tackle the motivating example from Frozen Lake and detail how to find strategies that maximize f, the probability of reaching a set of target states while minimizing the expected number of steps to reach them, encoded as g. In this context, $\overline{\Sigma_f}$ will be the set of strategies that only play actions used by at least one optimal strategy for reachability. In particular, $\Sigma_f \subset \overline{\Sigma_f}$ as an action may be played by an optimal strategy despite making no progress towards the target (a self-loop for example). Secondly, we also consider the problem of maximizing the probability of remaining in a safe set of states, encoded as f, while minimizing the long-run average cost along safe paths, encoded as g. In this context, $\overline{\Sigma_f} = \Sigma_f$ is obtained as the set of strategies that have maximal probability of staying safe. Note that, while the second problem could be approached in using the shielding framework, it is not clear how to obtain an exact representation of the set Σ_f of all optimal

4 Busatto-Gaston et al.

strategies for the reachability objective f in the first problem. Our two-stage technique overcomes this by overapproximating the set and leveraging the fact that g is biased towards f.

In both cases, our solution to these (lexicographic) bi-objective problems can be implemented by using two calls to STORM or PRISM. We report on experimental results for the Frozen Lake example that validate the need and practicality of our approach. Finally, we discuss other instances of multi-objective problems where our approach naturally generalizes.

Related works The strategy synthesis problem in MDPs (or stochastic games, their 2.5-players extension) can be defined for a wide variety of temporal objectives and quantitative rewards. Multi-objective problems are particularly challenging, as they need to optimize for multiple, potentially conflicting, goals. [8] detailed a strategy synthesis algorithm for lexicographic combinations of ω regular objectives. This problem has also been studied with model-free, reinforcement learning approaches [13]. However, these approaches do not consider objectives that maximize quantitative rewards, and cannot optimize for properties such as the time to reach a target. In [5], one can mix LTL objectives with mean-payoff rewards and in [16] a lexicographic combination of discountedsum rewards is considered. Moreover, a discounted semantics of LTL⁶ is studied in [1], and can be used as a way to optimize for the time until a target is reached. Combinations of LTL and total-reward objectives have been considered in works such as [12] and [11], under assumptions that exclude our problem. Indeed, while minimizing the time to reach a target can be encoded as optimizing the totalreward of a slightly modified structure (where costs are 1 at every move before the target is reached then 0 forever), these works are not directly applicable to our problem: applying [12] requires the assumption that the optimal probability to reach a target is 1 in order to minimize the expected time to target, and [11] searches for a strategy on the Pareto frontier instead of optimizing for a lexicographic combination of objectives.

Note that minimizing the time to reach a target is only well-defined under the condition that the target is reached, so that our example requires studying conditional probabilities. This notion has been studied in single-objective settings, so that for example probabilistic model-checkers can optimize for the (conditional) probability of satisfying an ω -regular event under the condition that another ω -regular event holds [3]. In particular, [4] details how to maximize the expected total-reward until a target is reached, under the assumption that the target is indeed reached with positive probability. This does not solve our motivating example however, as it may yield a strategy that is suboptimal for the probability of reaching the target. Finally, we note that tools such as [7] can handle settings similar to our second example (optimizing for safety and mean-payoff), but they do not consider conditional mean-payoff.

⁶ This allows one to express constraints on the number of steps needed to satisfy an Until operator.

Overall, our general two-stage technique covers combinations of objectives that are subcases of problems previously studied (e.g. in [8]) but it is also applicable to combinations not previously considered. Interestingly, and to the best of our knowledge, optimizing for a reachability objective while minimizing the conditional time to satisfy is not formally covered by previous work on multi-objective strategy synthesis, and is not an available feature of probabilistic model-checkers.

2 Preliminaries

A probability distribution on a countable set S is a function $d: S \to [0, 1]$ such that $\sum_{s \in S} d(s) = 1$. We denote the set of all probability distributions on set S by $\mathcal{D}(S)$. The support of a distribution $d \in \mathcal{D}(S)$ is $\mathsf{Supp}(d) = \{s \in S \mid d(s) > 0\}$.

2.1 Markov chain

Definition 1 (Markov chain). A (discrete-time) Markov chain or an MC is a tuple M = (S, P), where S is a countable set of states and P is a mapping from S to $\mathcal{D}(S)$.

For states $s, s' \in S$, P(s)(s') denotes the probability of moving from state s to state s' in a single transition and we denote this probability P(s)(s') as P(s, s').

For a Markov chain M, a finite path $\rho = s_0 s_1 \dots s_i$ of length i > 0 is a sequence of i+1 consecutive states such that for all $t \in [0, i-1], s_{t+1} \in \operatorname{Supp}(P(s_t))$. We also consider states to be paths of length 0. Similarly, An infinite path is an infinite sequence $\rho = s_0 s_1 s_2 \dots$ of states such that for all $t \in \mathbb{N}$, $s_{t+1} \in \operatorname{Supp}(P(s_t))$. For a finite or infinite path $\rho = s_0 s_1 \dots$, we denote its $(i+1)^{th}$ state by $\rho[i] = s_i$. We denote the last state of a finite path $\rho = s_0 s_1 \dots s_n$ by $\operatorname{last}(\rho) = s_n$. Let $\rho = s_0 s_1 \dots s_i$ and $\rho' = s'_0 s'_1 \dots s'_j$ be two paths such that $s_i = s'_0$. Then, $\rho \cdot \rho'$ denotes the path $s_0 s_1 \dots s_i s'_1 \dots s'_j$. For a finite or infinite path $\rho = s_0 s_1 \dots$, we denote its i-length prefix as $\rho_1 = s_0 a_0 s_1 \dots s_i$.

denote its *i*-length prefix as $\rho_{|_i} = s_0 a_0 s_1 \dots s_i$. For a finite path $\rho \in \mathsf{Paths}_M$, we use $\mathsf{Paths}_M^\omega(\rho)$ to denote the set of all paths $\rho' \in \mathsf{Paths}_M^\omega$ such that there exists $\rho'' \in \mathsf{Paths}_M^\omega$ with $\rho' = \rho \cdot \rho''$. $\mathsf{Paths}_M^\omega(\rho)$ is called the *cylinder set* of ρ .

The σ -algebra associated with the MC M is the smallest σ -algebra that contains the cylinder sets $\mathsf{Paths}^\omega_M(\rho)$ for all $\rho \in \mathsf{Paths}_M$. For a state s in S, a measure is defined for the cylinder sets as –

$$\mathbb{P}_{M,s}(\mathsf{Paths}_{M}^{\omega}(s_0s_1\dots s_i)) = \begin{cases} \prod_{t=0}^{i-1} P(s_t)(s_{t+1}) & \text{if } s_0 = s \\ 0 & \text{otherwise.} \end{cases}$$

We also have $\mathbb{P}_{M,s}(\mathsf{Paths}_M^\omega(s)) = 1$ and $\mathbb{P}_{M,s}(\mathsf{Paths}_M^\omega(s')) = 0$ for $s' \neq s$. This can be extended to a unique probability measure $\mathbb{P}_{M,s}$ on the aforementioned σ -algebra. In particular, if $\mathcal{C} \subseteq \mathsf{Paths}_M$ is a set of finite paths forming pairwise disjoint cylinder sets, then $\mathbb{P}_{M,s}(\cup_{\rho \in \mathcal{C}} \mathsf{Paths}_M^\omega(\rho)) = \sum_{\rho \in \mathcal{C}} \mathbb{P}_{M,s}(\mathsf{Paths}_M^\omega(\rho))$.

Moreover, if $\Pi \in \mathsf{Paths}_M^{\omega}$ is the complement of a measurable set Π' , then $\mathbb{P}_{M,s}(\Pi) = 1 - \mathbb{P}_{M,s}(\Pi')$.

2.2 Markov decision process

Definition 2 (Markov decision process). A Markov decision process or an MDP is a tuple $\mathcal{M} = (S, A, P)$, where S is a finite set of states, A is a finite set of actions, and P is a (partial) mapping from $S \times A$ to $\mathcal{D}(S)$.

P(s,a)(s') denotes the probability that action a in state s leads to state s' and we denote this probability P(s,a)(s') as P(s,a,s'). Note that not all actions may be legal from a state. Therefore, if an action a is legal from a state s, we will have $\sum_{s' \in S} P(s,a,s') = 1$. Otherwise, we will have P(s,a,s') is undefined (denoted by \bot) for all $s' \in S$.

The definitions and notations used for paths in Markov chain can be extended in the case of MDPs. In an MDP, a *path* is a sequence of states and actions.

For an MDP \mathcal{M} , a (probabilistic) strategy is a function σ : Paths $_{\mathcal{M}} \to \mathcal{D}(A)$ that maps a finite path ρ to a probability distribution in $\mathcal{D}(A)$. For a path $\rho \in \mathsf{Paths}_{\mathcal{M}}$ and a strategy σ , we will write $\sigma(\rho, a)$ in place of $\sigma(\rho)(a)$. A strategy σ is deterministic if the support of the probability distributions $\sigma(\rho)$ has size 1. A strategy σ is memoryless if $\sigma(\rho)$ depends only on $\mathsf{last}(\rho)$, i.e. if σ satisfies that for all $\rho, \rho' \in \mathsf{Paths}_{\mathcal{M}}$, $\mathsf{last}(\rho) = \mathsf{last}(\rho') \Rightarrow \sigma(\rho) = \sigma(\rho')$. We denote the set of all finite paths in \mathcal{M} starting from s following σ by $\mathsf{Paths}_{\mathcal{M}}(s, \sigma)$.

An MDP \mathcal{M} induced by a strategy σ defines an MC \mathcal{M}_{σ} . Intuitively, this is obtained by unfolding \mathcal{M} using the strategy σ and using the probabilities in \mathcal{M} to define the transition probabilities. Formally, $\mathcal{M}_{\sigma} = (\mathsf{Paths}_{\mathcal{M}}, P_{\sigma})$ where for all paths $\rho \in \mathsf{Paths}_{\mathcal{M}}$, $P_{\sigma}(\rho)(\rho \cdot as) = \sigma(\rho)(a) \cdot P(\mathsf{last}(\rho), a)(s)$. Thus, a state ρ in $\mathsf{Paths}_{\mathcal{M}}$ uniquely matches a finite path ρ' in \mathcal{M}_{σ} where $\mathsf{last}(\rho') = \rho$. This way when a strategy σ and a state s is fixed, the probability measure $\mathbb{P}_{\mathcal{M}_{\sigma},s}$ defined in \mathcal{M}_{σ} is also extended for paths in $\mathsf{Paths}_{\mathcal{M}}$. We write the expected value of a random variable X with respect to the probability distribution $\mathbb{P}_{\mathcal{M}_{\sigma},s}$ as $\mathbb{E}_{\mathcal{M}_{\sigma},s}(X)$. For the ease of notation, we write $\mathbb{P}_{\mathcal{M}_{\sigma},s}$ and $\mathbb{E}_{\mathcal{M}_{\sigma},s}$ as $\mathbb{P}_{\sigma,s}$ and $\mathbb{E}_{\sigma,s}$ respectively, if the MDP \mathcal{M} is clear from the context. Also, we write $\mathsf{Paths}_{\mathcal{M}_{\sigma}}^{\omega}(\rho)$ as $\mathsf{Cyl}_{\sigma}(\rho)$, if the MDP \mathcal{M} is clear from the context.

3 Length-optimal strategy for reachability

We begin by considering the multi-objective problem motivated by the game of frozen lake – the robot tries to reach a target with as few steps as possible while not compromising on the probability of reaching a target. More formally, in this section, we find a strategy in an MDP that minimizes the expected number of steps to reach some goal states among those strategies that maximize the probability of reaching the goal states.

We consider a set of target states $T \subseteq S$ in \mathcal{M} , and assume that every state in T is a sink state, that is, it has only one outgoing action to itself with

probability 1. Given a path ρ in an MC M=(S,P), we use $\operatorname{len}_T(\rho)$ to denote the length of the shortest prefix of ρ that reaches one of the states of T, that is, $\operatorname{len}_T(\rho)=i$ if $\rho[i]\in T$ and for all $j< i, \, \rho[j]\notin T$.

For an MDP $\mathcal{M} = (S, A, P)$, let $\mathbb{P}_{\sigma,s}(\lozenge T)$ be the probability of reaching a state in T, starting from $s \in S$, following the strategy σ in \mathcal{M} . Then, let $\mathsf{Val}_{\mathcal{M}}(s) = \max_{\sigma} \mathbb{P}_{\sigma,s}(\lozenge T)$ be the maximum probability to reach T from s, and $\Sigma_{\mathcal{M},s}(\lozenge T) = \arg \max_{\sigma} \mathbb{P}_{\sigma,s}(\lozenge T)$ be the set of all optimal strategies.

Problem statement.

Given an MDP \mathcal{M} , an initial state s_0 and a set of goal states T, our objective is to find a strategy that minimizes $\mathbb{E}_{\sigma,s_0}(\operatorname{len}_T \mid \Diamond T)$ among the strategies in $\Sigma_{\mathcal{M},s_0}(\Diamond T)$, that is, the strategies which maximize $\mathbb{P}_{\sigma,s_0}(\Diamond T)$.

For the rest of this section, we fix the MDP $\mathcal{M} = (S, A, P)$ and a set of target states $T \subseteq S$. Note that, in this case, the functions $\sigma \mapsto \mathbb{P}_{\sigma,s_0}(\lozenge T)$ and $\sigma \mapsto -\mathbb{E}_{\sigma,s_0}(\ln_T \mid \lozenge T)$ correspond to the two functions f and g, respectively, and the set $\Sigma_{\mathcal{M},s_0}(\lozenge T)$ corresponds to Σ_f , described in the introduction (Eq. 1).

3.1 Maximizing probability to reach a target

We denote the set $\{(s,a) \in S \times A \mid \mathsf{Val}_{\mathcal{M}}(s) = \sum_{s'} P(s,a,s') \cdot \mathsf{Val}_{\mathcal{M}}(s')\}$ by $\mathsf{Opt}_{\mathcal{M}}$. For $s \in S$, let $\mathsf{Opt}_{\mathcal{M}}(s)$ be the set $\{a \mid (s,a) \in \mathsf{Opt}_{\mathcal{M}}\}$. Finally, we use $\Sigma^{\mathsf{Opt}}_{\mathcal{M}}$ to represent the set of strategies that takes actions according to $\mathsf{Opt}_{\mathcal{M}}$, that is, $\Sigma^{\mathsf{Opt}}_{\mathcal{M}} = \{\sigma \mid \forall \rho, \forall a \in \mathsf{Supp}(\sigma(\rho)); (\mathsf{last}(\rho), a) \in \mathsf{Opt}_{\mathcal{M}}\}$.

Lemma 1. For every state $s \in S$ and for every $a \in A$,

$$\mathsf{Val}_{\mathcal{M}}(s) \ge \sum_{s'} P(s, a, s') \cdot \mathsf{Val}_{\mathcal{M}}(s') \,.$$

Proof. Suppose, there is a state $s \in S$ and an action $a \in A$ such that $\mathsf{Val}_{\mathcal{M}}(s) < \sum_{s'} P(s, a, s') \cdot \mathsf{Val}_{\mathcal{M}}(s')$. Now, consider the strategy σ' that takes action a from s and then from paths $s \cdot as'$ follows a strategy $\sigma_{s'} \in \mathcal{L}_{\mathcal{M},s'}(\lozenge T)$ that maximizes the probability to reach states in T from s'. Formally,

$$\sigma'(\rho) = \begin{cases} a & \text{if } \rho = s \\ \sigma_{s'}(\rho') & \text{if } \rho = s \cdot as' \cdot \rho' \end{cases}$$

Then, $\mathbb{P}_{\sigma',s}(\lozenge T) = \sum_{s'} P(s,a,s') \cdot \mathbb{P}_{\sigma_{s'},s'}(\lozenge T) = \sum_{s'} P(s,a,s') \cdot \mathsf{Val}_{\mathcal{M}}(s') > \mathsf{Val}_{\mathcal{M}}(s)$, which is a contradiction.

In the following lemma, we will show that $\Sigma_{\mathcal{M}}^{\mathsf{Opt}}$ would act as the set $\overline{\Sigma_f}$ from Eq. 2, an over-approximation of the set $\Sigma_f = \Sigma_{\mathcal{M},s_0}(\lozenge T)$.

Lemma 2. For every state $s \in S$, $\Sigma_{\mathcal{M},s}(\lozenge T) \subseteq \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$.

Proof. Towards a contradiction, suppose that, there is a strategy $\sigma^* \in \Sigma_{\mathcal{M},s}(\lozenge T)$ such that $\sigma^* \notin \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$. Then there exists a path ρ and an action $a \in \mathsf{Supp}(\sigma^*(\rho))$ such that $(\mathsf{last}(\rho), a) \not\in \mathsf{Opt}_{\mathcal{M}}$. Let $\mathsf{last}(\rho) = t$. Then, from Lemma 1 and the fact that $(t, a) \not\in \mathsf{Opt}_{\mathcal{M}}$, we get -

$$\operatorname{Val}_{\mathcal{M}}(t) > \sum_{s'} P(t, a, s') \cdot \operatorname{Val}_{\mathcal{M}}(s'), \tag{3}$$

and for every other action $a' \neq a$,

$$Val_{\mathcal{M}}(t) \ge \sum_{s'} P(t, a', s') \cdot Val_{\mathcal{M}}(s'). \tag{4}$$

Consider the strategy $\overline{\sigma}^*$ that differs from σ^* only on paths with ρ as prefix: on every path having ρ as a prefix, $\overline{\sigma}^*$ takes the next action according to a strategy $\sigma_t \in \Sigma_{\mathcal{M},t}(\lozenge T)$ that maximizes the probability to reach a state in T from t, whereas, it takes action according to σ^* on every other path. Formally,

$$\overline{\sigma}^*(\rho') = \begin{cases} \sigma_t(\rho'') & \text{if } \rho' = \rho \cdot \rho'' \\ \sigma^*(\rho') & \text{otherwise.} \end{cases}$$

Note that, for every strategy σ , and for all $a' \in A$, $\mathbb{P}_{\mathcal{M}_{\sigma^*}, \rho \cdot a's'}(\lozenge T) \leq \mathsf{Val}_{\mathcal{M}}(s')$.

Therefore,
$$\mathbb{P}_{\sigma^*,\rho}(\lozenge T) = \sum_{a'} \left(\sigma^*(\rho,a') \cdot \sum_{s'} \left(P(t,a',s') \cdot \mathbb{P}_{\sigma^*,\rho \cdot a's'}(\lozenge T) \right) \right)$$
$$\leq \sum_{a'} \left(\sigma^*(\rho,a') \cdot \sum_{s'} \left(P(t,a',s') \cdot \mathsf{Val}_{\mathcal{M}}(s') \right) \right)$$
$$< \sum_{a'} \sigma^*(\rho,a') \cdot \mathsf{Val}_{\mathcal{M}}(t) \quad \text{[from Eq. 3 and 4]}$$
$$= \mathsf{Val}_{\mathcal{M}}(t)$$

So, $\mathbb{P}_{\overline{\sigma}^*,\rho}(\lozenge T) = \mathbb{P}_{\sigma_t,t}(\lozenge T) = \mathsf{Val}_{\mathcal{M}}(t) > \mathbb{P}_{\sigma^*,\rho}(\lozenge T)$. For a finite path ρ and an infinite path ρ' , we write $\rho \sqsubseteq \rho'$ if there exists an infinite path ρ'' such that $\rho' = \rho \cdot \rho''$. Now note that, for every strategy σ ,

$$\mathbb{P}_{\sigma,s}(\lozenge T) = \mathbb{P}_{\sigma,s}(\rho' \models \lozenge T \land \rho \sqsubseteq \rho') + \mathbb{P}_{\sigma,s}(\rho' \models \lozenge T \land \rho \not\sqsubseteq \rho')
= \mathbb{P}_{\sigma,s}(\mathsf{Cyl}_{\sigma}(p)) \cdot \mathbb{P}_{\sigma,\rho}(\lozenge T) + \mathbb{P}_{\sigma,s}(\rho' \models \lozenge T \land \rho \not\sqsubseteq \rho')$$
(5)

Since for any ρ' such that $\rho \not\sqsubseteq \rho'$, $\sigma^*(\rho') = \overline{\sigma}^*(\rho')$, we have $\mathbb{P}_{\sigma^*,s}(\mathsf{Cyl}_{\sigma}(\rho))$ is equal to $\mathbb{P}_{\overline{\sigma}^*,s}(\mathsf{Cyl}_{\overline{\sigma}^*}(\rho))$, and furthermore, $\mathbb{P}_{\sigma^*,s}(\rho' \models \Diamond T \land \rho \not\sqsubseteq \rho')$ is equal to $\mathbb{P}_{\overline{\sigma}^*,s}(\rho' \models \Diamond T \land \rho \not\sqsubseteq \rho')$. Plugging this into Eq. 5 for σ^* and $\overline{\sigma}^*$, and the fact that $\mathbb{P}_{\sigma^*,\rho}(\Diamond T) < \mathbb{P}_{\overline{\sigma}^*,\rho}(\Diamond T)$, we conclude $\mathbb{P}_{\sigma^*,s}(\Diamond T) < \mathbb{P}_{\overline{\sigma}^*,s}(\Diamond T)$, which contradicts the fact that σ^* is an optimal strategy.

3.2 Minimizing expected conditional length to target

In the following, we propose a simple two-step pruning algorithm to solve the multi-objective problem defined earlier in this section. Towards that direction, we first modify the given MDP \mathcal{M} in the following manner.

Definition 3. We define the pruned MDP $\mathcal{M}' = (S', A, P')$ with $S' = \{s \in S \mid Val_{\mathcal{M}}(s) > 0\}$ and P' constructed from P in the following way:

$$P'(s, a, s') = \begin{cases} P(s, a, s') \cdot \frac{\mathsf{Val}_{\mathcal{M}}(s')}{\mathsf{Val}_{\mathcal{M}}(s)} & \textit{if } (s, a) \in \mathsf{Opt}_{\mathcal{M}} \textit{ and } s \in S' \\ \bot & \textit{otherwise}. \end{cases}$$

Note that $\mathcal{M}' = (S', A, P')$ is well-defined, since P' is a probability distribution. Indeed, $\sum_{s'} P'(s, a, s') = \sum_{s'} P(s, a, s') \cdot \frac{\mathsf{Val}_{\mathcal{M}}(s')}{\mathsf{Val}_{\mathcal{M}}(s)} = \frac{\mathsf{Val}_{\mathcal{M}}(s)}{\mathsf{Val}_{\mathcal{M}}(s)} = 1$. From the construction of \mathcal{M}' , we get that the set $\Sigma(\mathcal{M}')$ of all strategies

From the construction of \mathcal{M}' , we get that the set $\Sigma(\mathcal{M}')$ of all strategies in \mathcal{M}' is, in fact, $\Sigma_{\mathcal{M}}^{\mathsf{Opt}}$. Following similar notation as introduced earlier, for a strategy $\sigma \in \Sigma(\mathcal{M}')$, we write $\mathbb{P}_{\mathcal{M}'_{\sigma},s}$ and $\mathbb{E}_{\mathcal{M}'_{\sigma},s}$ as $\mathbb{P}'_{\sigma,s}$ and $\mathbb{E}'_{\sigma,s}$, respectively. Also, we write $\mathsf{Paths}_{\mathcal{M}'_{\varepsilon}}(\rho)$ as $\mathsf{Cyl}'_{\sigma}(\rho)$.

We now have all the ingredients to present the algorithm:

Algorithm 1

Input: $\mathcal{M} = (S, A, P), s_0 \in S \text{ and } T \subseteq S.$

- 1: Create MDP $\mathcal{M}' = (S', A, P')$ according to Definition 3.
- 2: Find a strategy σ^* that minimizes the expected length in \mathcal{M}' :

$$\sigma^* \in \operatorname{arg\,min}_{\sigma} \mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T)$$
.

3: return σ^* .

Note that, the strategies present in the pruned MDP \mathcal{M}' contain every strategy of \mathcal{M} that optimizes the probability of reaching a target (Lemma 2). To show that Algorithm 1 indeed returns a length-optimal strategy maximizing the probability of reachability in \mathcal{M} , we need to show the following:

- the strategy given by Algorithm 1 is indeed a strategy that optimizes the probability to reach a target, and
- for every strategy $\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)$, the conditional expected length to a target state $\mathbb{E}_{\sigma,s_0}(\operatorname{len}_T | \lozenge T)$ in \mathcal{M} is the same as $\mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T)$ in \mathcal{M}' . Therefore, it is enough to minimize the expected length in \mathcal{M}' .

We first show a relation between the measures of cylinder sets in \mathcal{M} and \mathcal{M}' .

Lemma 3. For every strategy $\sigma \in \varSigma_{\mathcal{M}}^{\mathsf{Opt}}$ and for every path $\rho = s_0 a_0 s_1 \dots s_n \in ((S' \setminus T) \cdot A)^*T \cap \mathsf{Paths}_{\mathcal{M}'}(s_0, \sigma), \ \mathbb{P}'_{\sigma, s_0}(\mathsf{Cyl}'_{\sigma}(\rho)) = \frac{\mathbb{P}_{\sigma, s_0}(\mathsf{Cyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)}.$

Proof. As $s_n \in T$, $\mathsf{Val}_{\mathcal{M}}(s_n) = 1$. So,

$$\begin{split} \mathbb{P}_{\sigma,s_0}'(\mathsf{Cyl}_\sigma'(\rho)) &= \prod_{i=0}^{n-1} \sigma(p_{|i},a_i) \cdot P'(s_i,a_i,s_{i+1}) \\ &= \prod_{i=0}^{n-1} \sigma(p_{|i},a_i) \cdot P(s_i,a_i,s_{i+1}) \cdot \frac{\mathsf{Val}_\mathcal{M}(s_{i+1})}{\mathsf{Val}_\mathcal{M}(s_i)} \end{split}$$

$$= \mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_\sigma(\rho)) \cdot \frac{\mathsf{Val}_{\mathcal{M}}(s_n)}{\mathsf{Val}_{\mathcal{M}}(s_0)} = \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_\sigma(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)} \,. \hspace{1cm} \Box$$

Using Lemma 3 we will prove that (cf. Corollary 1) every strategy that maximizes the probability of reaching a target state in \mathcal{M} , reaches a target state in \mathcal{M}' with probability 1, and vice versa.

Lemma 4. For every strategy $\sigma \in \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$, $\mathbb{P}'_{\sigma,s_0}(\lozenge T) = \frac{\mathbb{P}_{\sigma,s_0}(\lozenge T)}{\mathsf{Val}_{\mathcal{M}}(s_0)}$.

Proof. Note that, $\mathsf{Paths}_{\mathcal{M}'}(s_0) \cap ((S' \setminus T) \cdot A)^*T = \mathsf{Paths}_{\mathcal{M}}(s_0) \cap ((S \setminus T) \cdot A)^*T$, since in the construction of \mathcal{M}' we only remove states of \mathcal{M} from which no state in T is reachable. Therefore, using Lemma 3, we get:

$$\begin{split} \mathbb{P}'_{\sigma,s_0}(\lozenge T) &= \sum_{\rho \in \mathsf{Paths}_{\mathcal{M}'}(s_0) \cap ((S' \backslash T)A)^*T} \mathbb{P}'_{\sigma,s_0}(\mathsf{Cyl}'_{\sigma}(\rho)) \\ &= \sum_{\rho \in \mathsf{Paths}_{\mathcal{M}}(s_0) \cap ((S \backslash T)A)^*T} \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)} \\ &= \frac{\mathbb{P}_{\sigma,s_0}(\lozenge T)}{\mathsf{Val}_{\mathcal{M}}(s_0)} \,. \end{split}$$

Corollary 1. For every $\sigma \in \Sigma(\mathcal{M})$, $\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)$ iff $\mathbb{P}'_{\sigma,s_0}(\lozenge T) = 1$.

Since for every $\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)$, $\mathbb{P}_{\sigma,s_0}(\lozenge T \mid \lozenge T) = 1$, we can write:

$$\begin{split} \mathbb{E}_{\sigma,s_0}(\operatorname{len}_T \mid \lozenge T) &= \sum_{r=0}^\infty r \cdot \frac{\mathbb{P}_{\sigma,s_0}(\{\rho \mid \rho \models \lozenge T \wedge \operatorname{len}_T(\rho) = r\})}{\mathbb{P}_{\sigma,s_0}(\lozenge T)} \\ &= \sum_{r=0}^\infty r \cdot \sum_{\rho \in \mathsf{Paths}_{\mathcal{M}}(s_0) \cap ((S \backslash T)A)^*T : \operatorname{len}_T(\rho) = r} \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_\sigma(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)} \,. \end{split}$$

We now relate the expected length of reaching a target state in \mathcal{M}' with the expected conditional length of reaching a target state in \mathcal{M} .

Lemma 5. For any strategy $\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)$, $\mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T) = \mathbb{E}_{\sigma,s_0}(\operatorname{len}_T | \lozenge T)$.

Proof. Using $\mathsf{Paths}_{\mathcal{M}'}(s_0) \cap ((S' \setminus T) \cdot A)^*T = \mathsf{Paths}_{\mathcal{M}}(s_0) \cap ((S \setminus T) \cdot A)^*T$, Lemma 3 and Corollary 1, we get:

$$\begin{split} \mathbb{E}'_{\sigma,s_0}(\text{len}_T) &= \sum_{r=0}^{\infty} r \cdot \mathbb{P}'_{\sigma,s_0}(\{\rho \mid \rho \models \Diamond T \wedge \text{len}_T(\rho) = r\}) \\ &= \sum_{r=0}^{\infty} r \cdot \sum_{\rho \in \mathsf{Paths}_{\mathcal{M}'}(s_0) \cap ((S' \backslash T)A)^*T : \text{len}_T(\rho) = r} \mathbb{P}'_{\sigma,s_0}(\mathsf{Cyl}'_{\sigma}(\rho)) \\ &= \sum_{r=0}^{\infty} r \cdot \sum_{\rho \in \mathsf{Paths}_{\mathcal{M}}(s_0) \cap ((S \backslash T)A)^*T : \text{len}_T(\rho) = r} \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)} \\ &= \mathbb{E}_{\sigma,s_0}(\text{len}_T \mid \Diamond T). \end{split}$$

Finally, we prove the correctness of Algorithm 1:

Theorem 1. Given an MDP $\mathcal{M} = (S, A, P)$, a state $s_0 \in S$ and $T \subseteq S$, let σ^* be the strategy returned by Algorithm 1. Then,

1.
$$\mathbb{P}_{\sigma^*,s_0}(\lozenge T) = \mathsf{Val}_{\mathcal{M}}(s_0).$$

2. $\mathbb{E}_{\sigma^*,s_0}(\operatorname{len}_T | \lozenge T) = \min_{\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)} \mathbb{E}_{\sigma,s_0}(\operatorname{len}_T | \lozenge T)$

Proof. From Corollary 1, we get that $\mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T) \neq \infty$ iff $\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)$. So if $\sigma^* \notin \Sigma_{\mathcal{M},s_0}(\lozenge T)$, then $\mathbb{E}'_{\sigma^*,s_0}(\operatorname{len}_T) = \infty$. But since for any strategy σ in $\Sigma_{\mathcal{M},s_0}(\lozenge T)$, $\mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T) < \infty$, it contradicts the fact that σ^* minimizes $\mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T)$. Therefore, $\sigma^* \in \Sigma_{\mathcal{M},s_0}(\lozenge T)$, and hence $\mathbb{P}_{\sigma^*,s_0}(\lozenge T) = \mathsf{Val}_{\mathcal{M}}(s_0)$. From Lemma 5, we get for any $\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)$,

$$\mathbb{E}_{\sigma,s_0}(\operatorname{len}_T \mid \lozenge T) = \mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T)$$

$$\Longrightarrow \underset{\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)}{\operatorname{arg\,min}} \mathbb{E}_{\sigma,s_0}(\operatorname{len}_T \mid \lozenge T) = \underset{\sigma \in \Sigma_{\mathcal{M},s_0}(\lozenge T)}{\operatorname{arg\,min}} \mathbb{E}'_{\sigma,s_0}(\operatorname{len}_T)$$

Hence,
$$\sigma^* \in \arg\min_{\sigma \in \Sigma_{\mathcal{M}, s_0}(\lozenge T)} \mathbb{E}_{\sigma, s_0}(\operatorname{len}_T \mid \lozenge T)$$
 and therefore, we conclude,
$$\mathbb{E}_{\sigma^*, s_0}(\operatorname{len}_T \mid \lozenge T) = \min_{\sigma \in \Sigma_{\mathcal{M}, s_0}(\lozenge T)} \mathbb{E}_{\sigma, s_0}(\operatorname{len}_T \mid \lozenge T).$$

4 Experimental Results

We have made a prototype implementation of the pruning-based algorithm (Algorithm 1) described in Section 3. In this section, we compare the performance (expected number of steps to reach the goal states) of our algorithm with the strategies generated by Storm that (only) maximize the probability of reaching the goal states.

In our MDP, when the robot tries to move by picking a direction, the next state is determined randomly over the neighbouring positions of the robot, according to the following distribution weights: the intended direction gets a weight of 10, and other directions that are not a wall and not the reverse direction of the intended one get a weight of 1, the distribution is then normalized so that the weights sum up to 1.

We generated 100 layouts of size 10×10 where we placed walls in (i) each cell in the border of the grid and (ii) with probability 0.1, at each of other cells. We then placed holes in the remaining empty cells with the same probability. Finally, we chose the position of the target and the starting position from the remaining empty cells uniformly at random.

From these layouts, we constructed MDPs described in the PRISM language, a format supported by STORM. For each MDP, we extracted two strategies: (i) a strategy $\sigma_{\text{Storm}} \in \Sigma_{\mathcal{M},s}(\lozenge T)$ that is produced by STORM that optimizes the probability to reach the target, and (ii) σ_{DistOpt} , a strategy that is derived from Algorithm 1. Note that, both of these strategies are optimal for the probability to reach the target, however, the first strategy does not focus on optimizing the length to reach the target. For both of these strategies, we calculate the expected conditional distance to the target in their induced Markov chains. Table 1 reports

layouts (\mathcal{M})	$Val_{\mathcal{M}}(s_0, \lozenge T)$	Shortest distance	$v_{DistOpt}$	v_{Storm}
1	0.66	9	76.48	76.48
2	0.52	18	299.75	629.16
3	1.00	2	2.40	12.12
4	1.00	3	3.44	34.47
5	1.00	6	7.71	137.56
6	0.68	10	264.04	9598.81
7	1.00	5	112.69	9367.02
8	0.91	10	11.49	5879.63
9	1.00	3	3.66	5711.76
10	0.91	5	2.89	149357.57

Table 1. Comparison of the expected conditional length to reach the target for the strategies given by Algorithm 1 $(v_{DistOpt})$ and STORM (v_{Storm}) on some of the randomly generated layouts, sorted by their ratio. 'Shortest distance' refer to the length of the shortest path to the target (without considering the stochastic dynamics of Frozen Lake) and 'Val $_{\mathcal{M}}(s_0, \lozenge T)$ ' represents the maximum probability of reaching the target from the initial position of the robot (s_0) .

on our experimental results for a representative subset of the 100 layouts we generated, one of each decile (one layout from the 10 best percents, one from the 10-20% range, etc). Observe that the strategy given by Algorithm 1 does not necessarily suggest following the shortest path, as this may not optimize the first objective (reaching the target with maximum probability). For example, in the layout in Figure 1, the 'shortest' path to the target has length 10. But if we need to maximize the probability to reach the target, from the cell in the grid marked with 1, instead of going right, a better strategy would be to keep going to the cell above and then coming back. This way, the agent will avoid the hole below with certainty, and will eventually go to the right. This is the strategy that Algorithm 1 provides, which has expected conditional length to the target 33.85. On the other hand, the expected conditional length to the target while following the optimal strategy produced by STORM is much larger (345.34). This is because it asks the robot to loop in the 6×3 area in the left. Because of the stochastic dynamics it eventually leaves this area and reaches the target, but it may take a long time, increasing the expected conditional length.

While performing the experiments on the 100 randomly generated layouts, we observed that in 9 layouts out of 10, the expected conditional length (v_{Storm}) for the strategy σ_{Storm} is at least twice the expected conditional length (v_{DistOpt}) for the strategy σ_{DistOpt} . In 69% of the layouts, v_{Storm} values are 10 times worse than the v_{DistOpt} values. In the worst cases (23% of the layouts), v_{Storm} values are at least a 1000 times worse than the v_{DistOpt} values.

5 Safety and Expected Mean Payoff

In this section, we consider another multi-objective problem – as a first objective, we maximize the probability of avoiding a set of states in an MDP, and as

a second objective, we maximize the expected conditional Mean Payoff. We propose a pruning-based algorithm, similar to Algorithm 1, to solve this problem.

For this section, we augment the definition of an MDP \mathcal{M} with a reward function $R: S \times A \to \mathbb{R}$, where S, A and P are the same as in the previous sections. Furthermore, we consider a set of states $\mathsf{Bad} \subset S$ in \mathcal{M} and assume that every state in Bad is a sink state.

For an MDP $\mathcal{M}=(S,A,P,R)$, let $\mathbb{P}_{\mathcal{M}_{\sigma},s}(\Box\neg\mathsf{Bad})$ be the probability of avoiding all states in Bad , starting from $s\in S$, following the strategy σ in \mathcal{M} . Then, let $\mathsf{Val}_{\mathcal{M}}(s)=\max_{\sigma}\mathbb{P}_{\mathcal{M}_{\sigma},s}(\Box\neg\mathsf{Bad})$ be the maximum probability to avoid Bad from s, and $\mathcal{L}_{\mathcal{M},s}(\Box\neg\mathsf{Bad})=\arg\max_{\sigma}\mathbb{P}_{\mathcal{M}_{\sigma},s}(\Box\neg\mathsf{Bad})$ be the set of all optimal strategies for safety.

To formally define the second objective, we first define the total reward of horizon n for a path $\rho = s_0 a_0 \dots$ as $\operatorname{Rew}_n(\rho) = \sum_{i=0}^{n-1} R(s_i, a_i)$. Then, for a strategy σ and a state s, the expected mean-payoff is defined as

$$\mathbb{E}_{\sigma,s}(\mathsf{MP}) = \liminf_{n \to \infty} \frac{1}{n} \mathbb{E}_{\sigma,s}(\mathsf{Rew}_n)$$
.

We use $\mathbb{E}_{\sigma,s}(\mathsf{Rew}_n \mid \Box \neg \mathsf{Bad})$ to denote the expected conditional finite horizon reward. Then the expected conditional mean-payoff is defined as

$$\mathbb{E}_{\sigma,s}(\mathsf{MP} \mid \Box \neg \mathsf{Bad}) = \liminf_{n \to \infty} \frac{1}{n} \mathbb{E}_{\sigma,s}(\mathsf{Rew}_n \mid \Box \neg \mathsf{Bad}) \,.$$

Intuitively, it represents the expected mean-payoff one would obtain by following the strategy σ and staying safe.

Problem statement.

Given an MDP \mathcal{M} , an initial state s_0 and a set of states Bad , our objective is to find a strategy that maximizes $\mathbb{E}_{\mathcal{M}_{\sigma},s_0}(\mathsf{MP} \mid \Box \neg \mathsf{Bad})$ among the strategies in $\Sigma_{\mathcal{M},s_0}(\Box \neg \mathsf{Bad})$, that is, the strategies which maximize $\mathbb{P}_{\mathcal{M}_{\sigma},s_0}(\Box \neg \mathsf{Bad})$.

For the rest of this section, we fix the MDP $\mathcal{M} = (S, A, P, R)$ and a set of bad states $\mathsf{Bad} \subset S$. Note that, in this case, the functions $\sigma \mapsto \mathbb{P}_{\sigma,s_0}(\Box \neg \mathsf{Bad})$ and $\sigma \mapsto \mathbb{E}_{\sigma,s_0}(\mathsf{MP} \mid \Box \neg \mathsf{Bad})$ correspond to the two functions f and g, respectively, and $\Sigma_{\mathcal{M},s_0}(\Box \neg \mathsf{Bad})$ corresponds to Σ_f , described in the introduction (Eq. 1).

5.1 Maximizing probability of staying safe

We denote the set $\{(s,a) \in S \times A \mid \mathsf{Val}_{\mathcal{M}}(s) = \sum_{s'} P(s,a,s') \cdot \mathsf{Val}_{\mathcal{M}}(s')\}$ using $\mathsf{Opt}_{\mathcal{M}}$. For $s \in S$, let $\mathsf{Opt}_{\mathcal{M}}(s)$ be the set $\{a \mid (s,a) \in \mathsf{Opt}_{\mathcal{M}}\}$. Finally, we use $\varSigma^{\mathsf{Opt}}_{\mathcal{M}}$ to represent the set of strategies that takes actions according to $\mathsf{Opt}_{\mathcal{M}}$, that is, $\varSigma^{\mathsf{Opt}}_{\mathcal{M}} = \{\sigma \mid \forall \rho, \forall a \in \mathsf{Supp}(\sigma(\rho)); (\mathsf{last}(\rho), a) \in \mathsf{Opt}_{\mathcal{M}}\}$.

We first state the following results, analogous to Lemma 1 and 2 respectively, which can be proved similarly as in the case of reachability.

Lemma 6. For every state $s \in S \setminus \mathsf{Bad}$ and for every action a,

$$\operatorname{Val}_{\mathcal{M}}(s) \geq \sum_{s'} P(s, a, s') \cdot \operatorname{Val}_{\mathcal{M}}(s')$$
.

Lemma 7. For every state $s \in S$, $\Sigma_{\mathcal{M},s}(\Box \neg \mathsf{Bad}) \subseteq \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$.

Here note that $\varSigma_{\mathcal{M}}^{\mathsf{Opt}}$ acts as the set $\overline{\varSigma_f}$ and $\varSigma_{\mathcal{M},s_0}(\Box \neg \mathsf{Bad})$ as \varSigma_f from Eq. 2. Furthermore, we will show that, unlike reachability, in this case, the other direction of the containment also holds:

Lemma 8. For every state $s \in S$, $\Sigma_{\mathcal{M},s}(\Box \neg \mathsf{Bad}) \supseteq \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$.

In order to prove Lemma 8, we first develop a few intermediate results. We start with defining the following notations:

$$\begin{split} \mathsf{UPre}^0(\mathsf{Bad}) &= \mathsf{Bad}, \quad \mathsf{UPre}^{i+1}(\mathsf{Bad}) = \{s \mid \forall a, \exists s' \in \mathsf{UPre}^i(\mathsf{Bad}), P(s,a,s') > 0\}, \\ \mathsf{UPre}^*(\mathsf{Bad}) &= \bigcup_{i=0}^\infty \mathsf{UPre}^i(\mathsf{Bad}) \,. \end{split}$$

Furthermore, we define $Good = S \setminus UPre^*(Bad)$, $V = S \setminus (Good \cup Bad)$.

Lemma 9. For every state $s \in S$, $Val_{\mathcal{M}}(s) = 1$ iff $s \in Good$.

Proof. For $s \in \mathsf{Good}$, $\exists a \text{ such that } \mathsf{Supp}(P(s,a)) \subseteq \mathsf{Good}$. This gives a strategy to surely avoid Bad , and hence $\mathsf{Val}_{\mathcal{M}}(s) = 1$.

If $s \notin \mathsf{Good}$, then either (i) $s \in \mathsf{Bad}$, in which case $\mathsf{Val}_{\mathcal{M}}(s) = 0$, or (ii) $s \in \mathsf{UPre}^*(\mathsf{Bad})$, and hence $s \in \mathsf{UPre}^i(\mathsf{Bad}) \setminus \mathsf{UPre}^{i-1}(\mathsf{Bad})$ for some i. Then, for every action a, $\mathsf{Supp}(P(s,a)) \cap \mathsf{UPre}^{i-1}(\mathsf{Bad}) \neq \emptyset$. This implies, for any strategy σ , there is a path from s of length at most i reaching Bad following σ . Since this path has a non-zero probability, we therefore get that $\mathsf{Val}_{\mathcal{M}}(s) < 1$.

For a strategy σ and a finite path ρ , we define the strategy σ_{ρ} as follows: for any finite path ρ' starting from last (ρ) , $\sigma_{\rho}(\rho') = \sigma(\rho \cdot \rho')$.

Lemma 10. For every strategy $\sigma \in \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$, and every finite path ρ in \mathcal{M} following σ , $\mathbb{P}_{\sigma_{\rho},\mathsf{last}(\rho)}(\Box \neg \mathsf{Bad}) = 1$ iff $\mathsf{last}(\rho) \in \mathsf{Good}$.

Proof. We denote $\mathsf{last}(\rho)$ by s. First, let $s \in \mathsf{Good}$. Then we can show that $\forall a \in \mathsf{Opt}_{\mathcal{M}}(s), \mathsf{Supp}(P(s,a)) \subseteq \mathsf{Good}$. Indeed, if there exists an action $a \in \mathsf{Opt}_{\mathcal{M}}(s)$ and a state $s' \in \mathsf{Supp}(P(s,a))$ such that $s' \notin \mathsf{Good}$, then from Lemma 9, $\mathsf{Val}(s') < 1$, which would further imply that

$$\mathsf{Val}_{\mathcal{M}}(s) = \sum_{s'} P(s, a, s') \cdot \mathsf{Val}_{\mathcal{M}}(s') < \sum_{s'} P(s, a, s') = 1 \,,$$

which contradicts the fact that $s \in \mathsf{Good}$ (using Lemma 9). So for every strategy σ in $\Sigma^{\mathsf{Opt}}_{\mathcal{M}}$, every path from s following σ_{ρ} only visits states from Good . Therefore, $\mathbb{P}_{\sigma_{\rho},s}(\Box \neg \mathsf{Bad}) = 1$.

To conclude, observe that if $s \in S \setminus \mathsf{Good}$, $\mathbb{P}_{\sigma_{\varrho},s}(\Box \neg \mathsf{Bad}) \leq \mathsf{Val}_{\mathcal{M}}(s) < 1$. \Box

In the following, for the ease of notation, for any state $s \in S$ and a strategy σ , we denote $\mathbb{P}_{\sigma,s}(\mathsf{Cyl}_{\sigma}(\rho))$ by $\mathbf{P}_{\sigma,s}(\rho)$. Recall that, for every action $a \in \mathsf{Opt}_{\mathcal{M}}(s)$, $\mathsf{Val}_{\mathcal{M}}(s) = \sum_{s'} P(s,a,s') \cdot \mathsf{Val}_{\mathcal{M}}(s')$. We can then expand $\mathsf{Val}_{\mathcal{M}}(s)$ as:

$$\mathsf{Val}_{\mathcal{M}}(s) = \sum_{a} \sigma(s,a) \mathsf{Val}_{\mathcal{M}}(s) = \sum_{a} \sigma(s,a) \sum_{s'} P(s,a,s') \cdot \mathsf{Val}_{\mathcal{M}}(s') \,.$$

We can generalize the above statement by unfolding $\mathsf{Val}_{\mathcal{M}}(\cdot)$ for n steps:

Lemma 11. For every state $s \in S$ and for every strategy $\sigma \in \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$,

$$\mathsf{Val}_{\mathcal{M}}(s) = \sum_{\rho \in (VA)^n V} \mathbf{P}_{\sigma,s}(\rho) \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho)) + \sum_{\rho \in (VA)^{< n} \mathsf{Good}} \mathbf{P}_{\sigma,s}(\rho)$$

The summation in the first term of the above expression is taken over all paths that reach neither Good nor Bad within n steps, whereas the summation in the second term is over all paths that reach some state in Good within n steps. The result in Lemma 11 follows from the following result:

Lemma 12. For every finite path $\rho = s_0 a_0 s_1 \dots s_n$ of length n and for every strategy σ in $\Sigma_{\mathcal{M}}^{\mathsf{Opt}}$, for all k < n:

$$\mathsf{Val}_{\mathcal{M}}(s_k) = \sum_{\rho' \in (VA)^{n-k}V} \mathbf{P}_{\sigma_{\rho_{|_k},s_k}}(\rho') \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho')) + \sum_{\rho' \in (VA)^{< n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{\rho_{|_k},s_k}}(\rho') \,.$$

Using Lemma 12, we can now prove Lemma 11:

Proof of Lemma 11. Putting k = 0 in Lemma 12, we get:

$$\mathsf{Val}_{\mathcal{M}}(s_0) = \sum_{\rho' \in (VA)^n V} \mathbf{P}_{\sigma, s_0}(\rho') \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho')) + \sum_{\rho' \in (VA)^{\leq n} \mathsf{Good}} \mathbf{P}_{\sigma, s_0}(\rho') \,. \qquad \Box$$

We now characterize $\mathbb{P}(\cdot)$ in the same way as we did for $\mathsf{Val}(\cdot)$. Note that, for any state s and any strategy σ , we can expand $\mathbb{P}_{\sigma,s}(\Box \neg \mathsf{Bad})$ as

$$\mathbb{P}_{\sigma,s}(\Box\neg\mathsf{Bad}) = \sum_{a} \sigma(s,a) \sum_{s'} P(s,a,s') \cdot \mathbb{P}_{\sigma_{sas'},s'}(\Box\neg\mathsf{Bad}) \,.$$

Analogous to Lemma 11, we can generalize this statement by unfolding $\mathbb{P}(\cdot)$ for n steps:

Lemma 13. For every state $s \in S$ and for every strategy $\sigma \in \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$,

$$\mathbb{P}_{\sigma,s}\big(\Box\neg\mathsf{Bad}\big) = \sum_{\rho\in(VA)^nV} \mathbf{P}_{\sigma,s}(\rho) \cdot \mathbb{P}_{\sigma_\rho,\mathsf{last}(\rho)}\big(\Box\neg\mathsf{Bad}\big) + \sum_{\rho\in(VA)^{< n}\mathsf{Good}} \mathbf{P}_{\sigma,s}(\rho) \,.$$

Lemma 14. For every $s \in S$, and every $\sigma \in \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$, $\mathsf{Val}_{\mathcal{M}}(s) = \mathbb{P}_{\sigma,s}(\Box \neg \mathsf{Bad})$.

Proof. If $s \in \mathsf{Good}$, $\mathsf{Val}_{\mathcal{M}}(s) = \mathbb{P}_{\sigma,s}(\Box \neg \mathsf{Bad}) = 1$. If $s \in \mathsf{Bad}$, $\mathsf{Val}_{\mathcal{M}}(s) = \mathbb{P}_{\sigma,s}(\Box \neg \mathsf{Bad}) = 0$. Finally, if $s \in V$, from Lemma 11 and Lemma 13,

$$\begin{split} \mathsf{Val}_{\mathcal{M}}(s) - \mathbb{P}_{\sigma,s}(\Box \neg \mathsf{Bad}) &= \sum_{\rho \in (VA)^n V} \mathbf{P}_{\sigma,s}(\rho) \cdot (\mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho)) - \mathbb{P}_{\sigma_\rho,\mathsf{last}(\rho)}(\Box \neg \mathsf{Bad})) \\ &< \sum_{\rho \in (VA)^n V} \mathbf{P}_{\sigma,s}(\rho) \ [\text{Using Lemma 10}] \end{split}$$

For $s \in \mathsf{UPre}^*(\mathsf{Bad})$, there is a path of length at most |V| reaching Bad in \mathcal{M}_{σ} . So $\lim_{n \to \infty} \sum_{\rho \in (VA)^n V} \mathbf{P}_{\sigma,s}(\rho) = 0$.

Lemma 8 follows directly from Lemma 14. Then, using Lemma 7 and 8, we conclude the following theorem:

Theorem 2. For every state $s \in S$, $\Sigma_{\mathcal{M},s}(\Box \neg \mathsf{Bad}) = \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$.

5.2 Maximizing expected conditional Mean Payoff

We propose a simple two-step pruning algorithm, similar to Algorithm 1, to solve the multi-objective problem defined by safety and mean-payoff. We first modify the given MDP \mathcal{M} in the following manner.

Definition 4. We define $\mathcal{M}' = (S', A, P', R')$ where $S' = \{s \in S \mid \mathsf{Val}_{\mathcal{M}}(s) > 0\}$, R' is the same as R restricted to S', and P' is defined as follows:

$$P'(s, a, s') = \begin{cases} P(s, a, s') \cdot \frac{\mathsf{Val}_{\mathcal{M}}(s')}{\mathsf{Val}_{\mathcal{M}}(s)} & \textit{if } (s, a) \in \mathsf{Opt}_{\mathcal{M}} \textit{ and } s \in S' \\ \bot & \textit{otherwise}. \end{cases}$$

Note that \mathcal{M}' is again well-defined. We now present the two-step algorithm:

Algorithm 2

Input: $\mathcal{M} = (S, A, P, R), s_0 \in S, \mathsf{Bad} \subseteq S$

- 1: Create the MDP $\mathcal{M}' = (S', A, P', R')$ according to Definition 4.
- 2: Find a strategy σ^* that maximizes the expected Mean Payoff in \mathcal{M}' :

$$\sigma^* \in \operatorname{arg\,max}_{\sigma} \mathbb{E}'_{\sigma,s_0}(\mathsf{MP})$$
.

3: return σ^* .

For a state s_0 , a strategy σ , and a finite path $\rho = s_0 a_0 s_1 \dots s_n \in (S'A)^* S' \cap \mathsf{Paths}_{\mathcal{M}'}(s_0, \sigma)$, we define, $\mathsf{GoodCyl}_{\sigma}(\rho) = \mathsf{Cyl}_{\sigma}(\rho) \cap \{\rho' \mid \rho' \models \Box \neg \mathsf{Bad}\}$. Then, using Lemma 14, we get that if $\sigma \in \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$, then

$$\mathbb{P}_{\sigma,s_0}(\mathsf{GoodCyl}_{\sigma}(\rho)) = \mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_{\sigma}(\rho)) \cdot \mathbb{P}_{\sigma_{\rho},s_n}(\Box \neg \mathsf{Bad}) = \mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_{\sigma}(\rho)) \cdot \mathsf{Val}_{\mathcal{M}}(s_n). \ \ (6)$$

Lemma 15. For every strategy $\sigma \in \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$, $s_0 \in S'$ and every finite path $\rho = s_0 a_0 s_1 \dots s_n \in (S'A)^*S' \cap \mathsf{Paths}_{\mathcal{M}'}(s_0, \sigma), \ \mathbb{P}'_{\sigma, s_0}(\mathsf{Cyl}'_{\sigma}(\rho)) = \frac{\mathbb{P}_{\sigma, s_0}(\mathsf{GoodCyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)}$.

Proof.

$$\begin{split} \mathbb{P}'_{\sigma,s_0}(\mathsf{Cyl}'_{\sigma}(\rho)) &= \prod_{i=0}^{n-1} \sigma(\rho_{|i},a_i) \cdot P'(s_i,a_i,s_{i+1}) \\ &= \prod_{i=0}^{n-1} \sigma(\rho_{|i},a_i) \cdot P(s_i,a_i,s_{i+1}) \cdot \frac{\mathsf{Val}_{\mathcal{M}}(s_{i+1})}{\mathsf{Val}_{\mathcal{M}}(s_i)} \\ &= \mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_{\sigma}(\rho)) \cdot \frac{\mathsf{Val}_{\mathcal{M}}(s_n)}{\mathsf{Val}_{\mathcal{M}}(s_0)} = \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{GoodCyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)} \quad \text{[from Eq. 6]} \ \Box \end{split}$$

We now show the following correlation between the expected mean-payoff in \mathcal{M}' and the expected conditional mean-payoff in \mathcal{M} :

Lemma 16. For every strategy σ , $\mathbb{E}'_{\sigma}(MP) = \mathbb{E}_{\sigma}(MP \mid \Box \neg \mathsf{Bad})$

Proof. For $r \in \mathbb{N}$, we define $\xi_r = \{ \rho \in \mathsf{Paths}_{\mathcal{M}}(s_0) \cap (SA)^n S \mid \mathsf{Rew}_n(\rho) = r \}$ and $\xi'_r = \{ \rho \in \mathsf{Paths}_{\mathcal{M}'}(s_0) \cap (S'A)^n S' \mid \mathsf{Rew}_n(\rho) = r \}$. From the definition of the conditional expected reward in \mathcal{M} , we get:

$$\begin{split} \mathbb{E}_{\sigma,s_0}(\mathsf{Rew}_n \mid \Box \neg \mathsf{Bad}) &= \sum_{r=0}^{\infty} r \cdot \frac{\mathbb{P}_{\sigma,s_0}(\{\rho \mid \mathsf{Rew}_n(\rho) = r\} \cap \Box \neg \mathsf{Bad})}{\mathbb{P}_{\sigma,s_0}(\Box \neg \mathsf{Bad})} \\ &= \sum_{r=0}^{\infty} r \cdot \sum_{\rho \in \xi_r} \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{Cyl}_{\sigma}(\rho) \cap \Box \neg \mathsf{Bad})}{\mathsf{Val}_{\mathcal{M}}(s_0)} \\ &= \sum_{r=0}^{\infty} r \cdot \sum_{\rho \in \xi_r} \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{GoodCyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)} \,. \end{split}$$

Then,
$$\mathbb{E}'_{\sigma,s_0}(\mathsf{Rew}_n) = \sum_{r=0}^{\infty} r \cdot \mathbb{P}'_{\sigma,s_0}(\{\rho \mid \mathsf{Rew}_n(\rho) = r\}) = \sum_{r=0}^{\infty} r \cdot \sum_{\rho \in \xi'_r} \mathbb{P}'_{\sigma,s_0}(\mathsf{Cyl}'_{\sigma}(\rho))$$

$$= \sum_{r=0}^{\infty} r \cdot \sum_{\rho \in \xi'_r} \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{GoodCyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)}$$

$$= \sum_{r=0}^{\infty} r \cdot \sum_{\rho \in \xi_r} \frac{\mathbb{P}_{\sigma,s_0}(\mathsf{GoodCyl}_{\sigma}(\rho))}{\mathsf{Val}_{\mathcal{M}}(s_0)}$$

$$= \mathbb{E}_{\sigma,s_0}(\mathsf{Rew}_n \mid \Box \neg \mathsf{Bad}) \tag{8}$$

The equality in Eq. 7 is due to the fact that for any finite path $\rho = s_0 \dots s_n \in (SA)^n S \setminus (S'A)^n S', \ \exists i \ \text{s.t.} \ \mathsf{Val}_{\mathcal{M}}(s_i) = 0, \ \text{which implies}, \ \mathbb{P}_{\sigma,s_0}(\mathsf{GoodCyl}_{\sigma}(\rho)) \leq \mathbb{P}_{\sigma,s_0}(\mathsf{GoodCyl}_{\sigma}(s_0 \dots s_i)) = \mathbb{P}_{\sigma,s_0 \dots s_i}(\Box \neg \mathsf{Bad}) \leq \mathsf{Val}_{\mathcal{M}}(s_i) = 0.$

Finally, dividing by n and taking limit on the both sides of Eq. 8, we get $\mathbb{E}'_{\sigma,s_0}(\mathsf{MP}) = \mathbb{E}_{\sigma,s_0}(\mathsf{MP} \mid \Box \neg \mathsf{Bad}).$

Now we prove the correctness of Algorithm 2:

Theorem 3. Given an MDP $\mathcal{M} = (S, A, P, R)$, a state $s_0 \in S$ and $\mathsf{Bad} \subset S$, let σ^* be the strategy returned by Algorithm 2. Then,

1.
$$\mathbb{P}_{\sigma^*,s_0}(\Box \neg \mathsf{Bad}) = \mathsf{Val}_{\mathcal{M}}(s_0).$$

2. $\mathbb{E}_{\sigma^*,s_0}(\mathsf{MP} \mid \Box \neg \mathsf{Bad}) = \max_{\sigma \in \Sigma_{\mathcal{M},s_0}(\Box \neg \mathsf{Bad})} \mathbb{E}_{\sigma,s_0}(\mathsf{MP} \mid \Box \neg \mathsf{Bad})$

Proof. From Theorem 2, for any σ in $\Sigma_{\mathcal{M}}^{\mathsf{Opt}}$, $\mathbb{P}_{\sigma,s_0}(\Box \neg \mathsf{Bad}) = \mathsf{Val}_{\mathcal{M}}(s_0)$. Note that a strategy in \mathcal{M}' would be in $\Sigma_{\mathcal{M}}^{\mathsf{Opt}}$. Therefore, $\mathbb{P}_{\sigma^*,s_0}(\Box \neg \mathsf{Bad}) = \mathsf{Val}_{\mathcal{M}}(s_0)$. From Lemma 16, we get for any σ ,

$$\begin{split} & \mathbb{E}_{\sigma,s_0}(\mathsf{MP} \mid \Box \neg \mathsf{Bad}) = \mathbb{E}'_{\sigma,s_0}(\mathsf{MP}) \\ \Rightarrow & \underset{\sigma \in \varSigma_{\mathcal{M},s_0}(\Box \neg \mathsf{Bad})}{\mathrm{arg}} \, \mathbb{E}_{\sigma,s_0}(\mathsf{MP} \mid \Box \neg \mathsf{Bad}) = \underset{\sigma \in \varSigma_{\mathcal{M},s_0}(\Box \neg \mathsf{Bad})}{\mathrm{arg}} \, \mathbb{E}'_{\sigma,s_0}(\mathsf{MP}) \end{split}$$

Hence,
$$\sigma^* \in \arg\max_{\sigma \in \Sigma_{\mathcal{M}, s_0}(\square \neg \mathsf{Bad})} \mathbb{E}_{\sigma, s_0}(\mathsf{MP} \mid \square \neg \mathsf{Bad})$$
 and therefore, we conclude, $\mathbb{E}_{\sigma^*, s_0}(\mathsf{MP} \mid \square \neg \mathsf{Bad}) = \max_{\sigma \in \Sigma_{\mathcal{M}, s_0}(\square \neg \mathsf{Bad})} \mathbb{E}_{\sigma, s_0}(\mathsf{MP} \mid \square \neg \mathsf{Bad}).$

6 Discussion

The work presented in this article proposes a pruning-based approach (Algorithms 1, 2) that can be used to solve certain multi-objective problems in MDPs. The algorithms work by first pruning the given MDP based on the first objective, and then solving the (possibly simplified) second objective on the pruned MDP. Note that optimizing the second objective in turn optimizes the first objective as per our assumptions.

The case where the first objective is to maximize the probability of reaching a set of (target) states in an MDP and the second objective is to minimize the conditional expected distance to reach the same set of states, has been discussed in Section 3. Note that one can consider more general (positive) cost functions and try to minimize the conditional expected cost to reach the goal states as a secondary objective, keeping the first objective unchanged. We expect that our technique can also be used to solve the following. In an MDP with a priority function defined on its states, the first objective can be to maximize the probability to satisfy the parity condition, that is, to maximize the probability of the event that the largest parity that occurs infinitely often is even. For the secondary objective, we minimize the expected conditional mean distance between a request (visiting an odd parity) and its answer (visiting a larger even parity). If a request is unanswered, we consider the distance to be 0 so as not to affect the conditional expectation.

Further, while we studied only two-dimensional lexicographic objectives for the sake of clarity and simplicity, we note that our work can be straight-forwardly extended to more than two reward structures. For example, one may want to optimize for safety first, reachability second, and minimal expected time to reach a target as a third objective. In this case, we would proceed in three steps: a first pruning of the MDP that solves the safety problem, a second pruning that over-approximate the winning strategies for reachability, and finally we would minimize the expected distance.

A Missing proofs of Section 5

A.1 Proof of Lemma 6

Suppose, there is a state $s \in S \setminus \mathsf{Bad}$ and an action $a \in A$ such that $\mathsf{Val}_{\mathcal{M}}(s) < \sum_{s'} P(s, a, s') \cdot \mathsf{Val}_{\mathcal{M}}(s')$. Now, consider the strategy σ' that takes action a from s and then from paths $s \cdot as'$ follows a strategy $\sigma_{s'} \in \Sigma_{\mathcal{M}, s'}(\Box \neg \mathsf{Bad})$ that maximizes the probability to avoid states in Bad . Formally,

$$\sigma'(\rho) = \begin{cases} a & \text{if } \rho = s \\ \sigma_{s'}(\rho') & \text{if } \rho = s \cdot as' \cdot \rho' \end{cases}$$

Then, we get the following: $\mathbb{P}_{\mathcal{M}_{\sigma'},s}(\Box \neg \mathsf{Bad}) = \sum_{s'} P(s,a,s') \cdot \mathbb{P}_{\sigma_{s'},s'}(\Box \neg \mathsf{Bad}) = \sum_{s'} P(s,a,s') \cdot \mathsf{Val}_{\mathcal{M}}(s') > \mathsf{Val}_{\mathcal{M}}(s)$, which is a contradiction.

A.2 Proof of Lemma 7

Suppose that there is a strategy $\sigma^* \in \Sigma_{\mathcal{M},s}(\Box \neg \mathsf{Bad})$ where there exists a path ρ and an action $a \in \mathsf{Supp}(\sigma^*(\rho))$ such that $(\mathsf{last}(\rho), a) \not\in \mathsf{Opt}_{\mathcal{M}}$. Let $\mathsf{last}(\rho) = t$. Assume that $\rho \models \Box \neg \mathsf{Bad}$. Then, from Lemma 6 and the fact that $(t, a) \not\in \mathsf{Opt}_{\mathcal{M}}$,

$$\mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho)) > \sum_{s'} P(t, a, s') \cdot \mathsf{Val}_{\mathcal{M}}(s')$$

and for every other action $a' \neq a$,

$$\mathsf{Val}_{\mathcal{M}}(t) \ge \sum_{s'} P(t, a', s') \cdot \mathsf{Val}_{\mathcal{M}}(s')$$
.

Consider the strategy σ'' which differs from σ^* only on paths with ρ as prefix: on every path having ρ as a prefix, σ'' takes the next action according to a strategy $\sigma_t \in \Sigma_{\mathcal{M},t}(\Box \neg \mathsf{Bad})$ that maximizes the probability to avoid states in Bad from $\mathsf{last}(\rho)$, whereas, it takes action according to σ^* on every other path. Formally,

$$\sigma''(\rho') = \begin{cases} \sigma_t(\rho'') & \text{if } \rho' = \rho \cdot \rho'' \\ \sigma^*(\rho') & \text{otherwise.} \end{cases}$$

Note that, for every strategy σ ,

$$\mathbb{P}_{\mathcal{M}_{\sigma},\rho}(\Box\neg\mathsf{Bad}) = \sum_{a'} \left(\sigma(\rho,a') \cdot \sum_{s'} \left(P(t,a',s') \cdot \mathbb{P}_{\mathcal{M}_{\sigma},\rho\cdot a's'}(\Box\neg\mathsf{Bad}) \right) \right).$$

Also, $\mathbb{P}_{\mathcal{M}_{\sigma^*}, \rho \cdot a's'}(\Box \neg \mathsf{Bad}) \leq \mathsf{Val}_{\mathcal{M}}(s')$ for all $a' \in A$. Therefore,

$$\mathbb{P}_{\mathcal{M}_{\sigma^*},\rho}(\Box\neg\mathsf{Bad}) = \sum_{a'} \left(\sigma^*(\rho,a') \cdot \sum_{s'} \left(P(t,a',s') \cdot \mathbb{P}_{\mathcal{M}_{\sigma^*},\rho \cdot a's'}(\Box\neg\mathsf{Bad})\right)\right)$$

$$\begin{split} & \leq \sum_{a'} \left(\sigma^*(\rho, a') \cdot \sum_{s'} \left(P(t, a', s') \cdot \mathsf{Val}_{\mathcal{M}}(s') \right) \right) \\ & < \sum_{a'} \sigma^*(\rho, a') \cdot \mathsf{Val}_{\mathcal{M}}(t) \\ & = \mathsf{Val}_{\mathcal{M}}(t) \end{split}$$

So, $\mathbb{P}_{\mathcal{M}_{\sigma''},\rho}(\Box\neg\mathsf{Bad})=\mathbb{P}_{\mathcal{M}_{\sigma_t},t}(\Box\neg\mathsf{Bad})=\mathsf{Val}_{\mathcal{M}}(t,T)>\mathbb{P}_{\mathcal{M}_{\sigma^*},\rho}(\Box\neg\mathsf{Bad}).$ Now note that, for any strategy σ ,

$$\begin{split} \mathbb{P}_{\mathcal{M}_{\sigma},s}(\Box\neg\mathsf{Bad}) &= \mathbb{P}_{\mathcal{M}_{\sigma},s}(\rho'\models\Box\neg\mathsf{Bad}\wedge\rho\sqsubseteq\rho') + \mathbb{P}_{\mathcal{M}_{\sigma},s}(\rho'\models\Box\neg\mathsf{Bad}\wedge\rho\not\sqsubseteq\rho') \\ &= \mathbb{P}_{\mathcal{M}_{\sigma},s}(\mathsf{Cyl}_{\sigma}(\rho))\cdot\mathbb{P}_{\mathcal{M}_{\sigma},\rho}(\Box\neg\mathsf{Bad}) + \mathbb{P}_{\mathcal{M}_{\sigma},s}(\rho'\models\Box\neg\mathsf{Bad}\wedge\rho\not\sqsubseteq\rho') \end{split}$$

As $\sigma^*(\rho') = \sigma''(\rho')$ for any ρ' such that $\rho \sqsubseteq \rho'$,

$$\mathbb{P}_{\mathcal{M}_{\sigma^*},s}((\mathsf{Cyl}_{\sigma^*}(\rho))) = \mathbb{P}_{\mathcal{M}_{\sigma''},s}((\mathsf{Cyl}_{\sigma''}(\rho))).$$

and

$$\mathbb{P}_{\mathcal{M}_{\sigma^*},s}(\rho'\models\Box\neg\mathsf{Bad}\wedge\rho\not\sqsubseteq\rho')=\mathbb{P}_{\mathcal{M}_{\sigma''},s}(\rho'\models\Box\neg\mathsf{Bad}\wedge\rho\not\sqsubseteq\rho')\,.$$

Then $\mathbb{P}_{\mathcal{M}_{\sigma^*},s}(\Box \neg \mathsf{Bad}) < \mathbb{P}_{\mathcal{M}_{\sigma''},s}(\Box \neg \mathsf{Bad})$, which cannot be true as σ^* is an optimal strategy. Therefore, $\Sigma_{\mathcal{M},s}(\Box \neg \mathsf{Bad}) \subseteq \Sigma_{\mathcal{M}}^{\mathsf{Opt}}$.

A.3 Proof of Lemma 12

We prove this by backward induction on k.

Base case: k = n - 1. If $s_{n-1} \in \mathsf{Good}$, then $\mathsf{Val}_{\mathcal{M}}(s_{n-1}) = 1$. If $s_{n-1} \in \mathsf{Bad}$, then $\mathsf{Val}_{\mathcal{M}}(s_{n-1}) = 0$. In both cases, the statement is trivially true. If $s_{n-1} \in V$,

$$\begin{split} \mathsf{Val}_{\mathcal{M}}(s_{n-1}) &= \sum_{a_{n-1}} \sigma(\rho_{|_{n-1}}, a_{n-1}) \sum_{s'_n} P(s_{n-1}, a_{n-1}, s'_n) \cdot \mathsf{Val}_{\mathcal{M}}(s'_n) \\ &= \sum_{\rho' \in \{s_{n-1}\}AS} \mathbf{P}_{\sigma_{\rho_{|_{n-1}}, s_{n-1}}}(\rho') \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho')) \\ &= \sum_{\rho' \in \{s_{n-1}\}AV} \mathbf{P}_{\sigma_{\rho_{|_{n-1}}, s_{n-1}}}(\rho') \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho')) + \\ &\sum_{\rho' \in \{s_{n-1}\}A\mathsf{Good}} \mathbf{P}_{\sigma_{\rho_{|_{n-1}}, s_{n-1}}}(\rho') \times 1 + \sum_{\rho' \in \{s_{n-1}\}A\mathsf{Bad}} \mathbf{P}_{\sigma_{\rho_{|_{n-1}}, s_{n-1}}}(\rho') \times 0 \\ &= \sum_{\rho' \in VAV} \mathbf{P}_{\sigma_{\rho_{|_{n-1}}, s_{n-1}}}(\rho') \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho')) + \sum_{\rho' \in VA\mathsf{Good}} \mathbf{P}_{\sigma_{\rho_{|_{n-1}}, s_{n-1}}}(\rho') \end{split}$$

Suppose the statement is true for k+1. Then,

$$\begin{split} \mathsf{Val}_{\mathcal{M}}(s_k) &= \sum_{a_k} \sigma(\rho_{|_k}, a_k) \sum_{s'_{k+1}} P(s_k, a_k, s'_{k+1}) \mathsf{Val}_{\mathcal{M}}(s'_{k+1}) \\ &= \sum_{a_k} \sigma(\rho_{|_k}, a_k) \left(\sum_{s'_{k+1} \in V} P(s_k, a_k, s'_{k+1}) \mathsf{Val}_{\mathcal{M}}(s'_{k+1}) + \right) \end{split}$$

$$\begin{split} &\sum_{s'_{k+1} \in \mathsf{Good}} P(s_k, a_k, s'_{k+1}) \mathsf{Val}_{\mathcal{M}}(s'_{k+1}) + \sum_{s'_{k+1} \in \mathsf{Bad}} P(s_k, a_k, s'_{k+1}) \mathsf{Val}_{\mathcal{M}}(s'_{k+1}) \\ &= \sum_{a_k} \sigma(\rho_{|_k}, a_k) \left(\sum_{s'_{k+1} \in V} P(s_k, a_k, s'_{k+1}) \mathsf{Val}_{\mathcal{M}}(s'_{k+1}) + \sum_{s'_{k+1} \in \mathsf{Good}} P(s_k, a_k, s'_{k+1}) \right) \\ &= \sum_{a_k} \sigma(\rho_{|_k}, a_k) \sum_{s'_{k+1} \in V} P(s_k, a_k, s'_{k+1}) \sum_{\rho' \in (\{s'_{k+1}\} \cdot A)^{n-k-1} \cdot V} \mathbf{P}_{\sigma_{\rho_{|_{k+1}}}, s'_{k+1}}(\rho') \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho')) \\ &+ \sum_{a_k} \sigma(\rho_{|_k}, a_k) \sum_{s'_{k+1} \in V} P(s_k, a_k, s'_{k+1}) \sum_{\rho' \in (\{s'_{k+1}\} \cdot A) \leq n-k-1} \cdot \mathsf{Good}} \mathbf{P}_{\sigma_{\rho_{|_k}+1}, s'_{k+1}}(\rho') \\ &+ \sum_{a_k} \sigma(\rho_{|_k}, a_k) \sum_{s'_{k+1} \in \mathsf{Good}} P(s_k, a_k, s'_{k+1}) \\ &= \sum_{\rho' \in (VA)^{n-k} V} \mathbf{P}_{\sigma_{\rho_{|_k}}, s_k}(\rho') \cdot \mathsf{Val}_{\mathcal{M}}(\mathsf{last}(\rho')) + \sum_{\rho' \in (VA)^{< n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{\rho_{|_k}}, s_k}(\rho') \,. \end{split}$$

A.4 Proof of Lemma 13

Here, for the ease of notation, we will use $\mathsf{Val}_{\sigma}(s)$ to denote $\mathbb{P}_{\sigma,s}(\Box \neg \mathsf{Bad})$.

Lemma 17. Let $\rho = s_0 a_0 s_1 \dots s_n$ be a finite path of length n. Let σ be a strategy in $\Sigma_{\mathcal{M}}^{\mathsf{Opt}}$. Then for all k < n:

$$\mathsf{Val}_{\sigma_{p_{|_k}}}(s_k) = \sum_{\rho' \in (VA)^{n-k}V} \mathbf{P}_{\sigma_{p_{|_k},s_k}}(\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k},\rho'}}(\mathsf{last}(\rho')) + \sum_{\rho' \in (VA)^{\leq n-k}\mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k},s_k}}(\rho')$$

Proof. We prove this by backward induction on k. For k = n - 1. If $s_{n-1} \in \mathsf{Good}$, then $\mathsf{Val}_{\mathcal{M}}(s_{n-1}) = 1$. If $s_{n-1} \in \mathsf{Bad}$, then $\mathsf{Val}_{\mathcal{M}}(s_{n-1}) = 0$. In both cases, the statement is trivially true. If $s_{n-1} \in V$,

$$\begin{split} \mathsf{Val}_{\sigma_{p}_{\mid_{n-1}}}(s_{n-1}) &= \sum_{a_{n-1}'} \sigma(p_{\mid_{n-1}}, a_{n-1}') \sum_{s_{n}'} P(s_{n-1}, a_{n-1}', s_{n}') \mathsf{Val}_{\sigma_{p}_{\mid_{n-1}} \cdot a_{n-1}' s_{n-1}'}(s_{n}') \\ &= \sum_{\rho' \in \{s_{n-1}\}AS} \mathbf{P}_{\sigma_{p}_{\mid_{n-1}}, s_{n-1}}(\rho') \cdot \mathsf{Val}_{\sigma_{p}_{\mid_{n-1}} \cdot \rho'}(\mathsf{last}(\rho')) \\ &= \sum_{\rho' \in \{s_{n-1}\}AV} \mathbf{P}_{\sigma_{p}_{\mid_{n-1}}, s_{n-1}}(\rho') \cdot \mathsf{Val}_{\sigma_{p}_{\mid_{n-1}} \cdot \rho'}(\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in \{s_{n-1}\}A\mathsf{Good}} \mathbf{P}_{\sigma_{p}_{\mid_{n-1}}, s_{n-1}}(\rho') \times 1 \\ &+ \sum_{\rho' \in \{s_{n-1}\}A\mathsf{Bad}} \mathbf{P}_{\sigma_{p}_{\mid_{n-1}}, s_{n-1}}(\rho') \times 0 \\ &= \sum_{\rho' \in VAV} \mathbf{P}_{\sigma_{p}_{\mid_{n-1}}, s_{n-1}}(\rho') \cdot \mathsf{Val}_{\sigma_{p}_{\mid_{n-1}} \cdot \rho'}(\mathsf{last}(\rho')) + \sum_{\rho' \in VA\mathsf{Good}} \mathbf{P}_{\sigma_{p}_{\mid_{n-1}}, s_{n-1}}(\rho') \end{split}$$

Suppose the statement is true for k + 1. Then, using Lemma 10,

$$\mathsf{Val}_{\sigma_{p_{|_{k}}}}(s_{k}) = \sum_{a'_{k}} \sigma(p_{|_{k}}, a'_{k}) \sum_{s'_{k+1}} P(s_{k}, a'_{k}, s'_{k+1}) \mathsf{Val}_{\sigma_{p_{|_{k}} \cdot a'_{k}} s'_{k+1}}(s'_{k+1})$$

$$\begin{split} &= \sum_{a_k} \sigma(p_{|_k}, a_k) \left(\sum_{s'_{k+1} \in V} P(s_k, a'_k, s'_{k+1}) \mathsf{Val}_{\sigma_{p_{|_k} \cdot a'_k s'_{k+1}}} (s'_{k+1}) \right. \\ &+ \sum_{s'_{k+1} \in \mathsf{Good}} P(s_k, a'_k, s'_{k+1}) \mathsf{Val}_{\sigma_{p_{|_k} \cdot a'_k s'_{k+1}}} (s'_{k+1}) \\ &+ \sum_{s'_{k+1} \in \mathsf{Bad}} P(s_k, a'_k, s'_{k+1}) \mathsf{Val}_{\sigma_{p_{|_k} \cdot a'_k s'_{k+1}}} (s'_{k+1}) \right) \\ &= \sum_{a_k} \sigma(p_{|_k}, a_k) \left(\sum_{s'_{k+1} \in V} P(s_k, a'_k, s'_{k+1}) \mathsf{Val}_{\sigma_{p_{|_k} \cdot a'_k s'_{k+1}}} (s'_{k+1}) \right. \\ &+ \sum_{s'_{k+1} \in \mathsf{Good}} P(s_k, a'_k, s'_{k+1}) \right) \\ &= \sum_{a_k} \sigma(p_{|_k}, a_k) \sum_{s'_{k+1} \in V} P(s_k, a'_k, s'_{k+1}) \times \\ &\left(\sum_{\rho' \in (VA)^{n-k-1}V} \mathbf{P}_{\sigma_{p_{|_k} \cdot a'_k s'_{k+1}, s_{k+1}}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot a'_k s'_{k+1} \cdot \rho'}} (\mathsf{last}(\rho')) \right. \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \\ &+ \sum_{\alpha_k} \sigma(p_{|_k}, a_k) \sum_{s'_{k+1} \in \mathsf{Good}} P(s_k, a'_k, s'_{k+1}) \\ &= \sum_{\rho' \in (VA)^{n-k} \mathsf{Val}_{n-k}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P}_{\sigma_{p_{|_k} \cdot s_k}} (\rho') \cdot \mathsf{Val}_{\sigma_{p_{|_k} \cdot \rho'}} (\mathsf{last}(\rho')) \\ &+ \sum_{\rho' \in (VA)^{n-k} \mathsf{Good}} \mathbf{P$$

Proof of Lemma 13. For k = 0 in Lemma 17, we get:

$$\mathsf{Val}_{\sigma}(s_0) = \sum_{p' \in (VA)^n V} \mathbf{P}_{\sigma,s_0}(p') \cdot \mathsf{Val}_{\sigma}(\mathsf{last}(p')) + \sum_{p' \in (VA)^{\leq n} \mathsf{Good}} \mathbf{P}_{\sigma,s_0}(p') \,. \quad \Box$$
