A (Slightly) Improved Approximation Algorithm for Metric TSP

Anna R. Karlin, Nathan Klein, and Shayan Oveis Gharan University of Washington

September 1, 2020

Abstract

For some $\epsilon > 10^{-36}$ we give a $3/2 - \epsilon$ approximation algorithm for metric TSP.

1 Introduction

One of the most fundamental problems in combinatorial optimization is the traveling salesperson problem (TSP), formalized as early as 1832 (c.f. [App+07, Ch 1]). In an instance of TSP we are given a set of n cities V along with their pairwise symmetric distances, $c: V \times V \to \mathbb{R}_{\geq 0}$. The goal is to find a Hamiltonian cycle of minimum cost. In the metric TSP problem, which we study here, the distances satisfy the triangle inequality. Therefore, the problem is equivalent to finding a closed Eulerian connected walk of minimum cost.¹

It is NP-hard to approximate TSP within a factor of $\frac{123}{122}$ [KLS15]. An algorithm of Christofides-Serdyukov [Chr76; Ser78] from four decades ago gives a $\frac{3}{2}$ -approximation for TSP (see [BS20] for a historical note about TSP). This remains the best known approximation algorithm for the general case of the problem despite significant work, e.g., [Wol80; SW90; BP91; Goe95; CV00; GLS05; BEM10; BC11; SWZ12; HNR17; HN19; KKO20].

In contrast, there have been major improvements to this algorithm for a number of special cases of TSP. For example, polynomial-time approximation schemes (PTAS) have been found for Euclidean [Aro96; Mit99], planar [GKP95; Aro+98; Kle05], and low-genus metric [DHM07] instances. In addition, the case of graph metrics has received significant attention. In 2011, the third author, Saberi, and Singh [OSS11] found a $\frac{3}{2} - \epsilon_0$ approximation for this case. Mömke and Svensson [MS11] then obtained a combinatorial algorithm for graphic TSP with an approximation ratio of 1.461. This ratio was later improved by Mucha [Muc12] to $\frac{13}{9} \approx 1.444$, and then by Sebö and Vygen [SV12] to 1.4.

In this paper we prove the following theorem:

Theorem 1.1. For some absolute constant $\epsilon > 10^{-36}$, there is a randomized algorithm that outputs a tour with expected cost at most $\frac{3}{2} - \epsilon$ times the cost of the optimum solution.

We note that while the algorithm makes use of the Held-Karp relaxation, we do not prove that the integrality gap of this polytope is bounded away from 3/2. We also remark that although our approximation factor is only slightly better than Christofides-Serdyukov, we are not aware of any example where the approximation ratio of the algorithm we analyze exceeds 4/3 in expectation.

Following a new exciting result of Traub, Vygen, Zenklusen [TVZ20] we also get the following theorem.

Theorem 1.2. For some absolute constant $\epsilon > 0$ there is a randomized algorithm that outputs a TSP path with expected cost at most $\frac{3}{2} - \epsilon$ times the cost of the optimum solution.

1.1 Algorithm

First, we recall the classical Christofides-Serdyukov algorithm: Given an instance of TSP, choose a minimum spanning tree and then add the minimum cost matching on the odd degree vertices of the tree. The algorithm we study is very similar, except we choose a random spanning tree based on the standard linear programming relaxation of TSP.

¹Given such an Eulerian cycle, we can use the triangle inequality to shortcut vertices visited more than once to get a Hamiltonian cycle.

Let x^0 be an optimum solution of the following TSP linear program relaxation [DFJ59; HK70]:

min
$$\sum_{u,v} x_{(u,v)} c(u,v)$$
s.t.,
$$\sum_{u} x_{(u,v)} = 2 \qquad \forall v \in V,$$

$$\sum_{u \in S, v \notin S} x_{(u,v)} \ge 2, \quad \forall S \subsetneq V,$$

$$x_{(u,v)} \ge 0 \qquad \forall u,v \in V.$$

$$(1)$$

Given x^0 , we pick an arbitrary node, u, split it into two nodes u_0 , v_0 and set $x_{(u_0,v_0)} = 1$, $c(u_0,v_0) = 0$ and we assign half of every edge incident to u to u_0 and the other half to v_0 . This allows us to assume without loss of generality that x^0 has an edge $e_0 = (u_0, v_0)$ such that $x_{e_0} = 1$, $c(e_0) = 0$.

Let $E_0 = E \cup \{e_0\}$ be the support of x^0 and let x be x^0 restricted to E and G = (V, E). x^0 restricted to E is in the spanning tree polytope (3).

For a vector $\lambda: E \to \mathbb{R}_{\geq 0}$, a λ -uniform distribution μ_{λ} over spanning trees of G = (V, E) is a distribution where for every spanning tree $T \subseteq E$, $\mathbb{P}_{\mu}[T] = \frac{\prod_{e \in T} \lambda_e}{\sum_{T'} \prod_{e \in T'} \lambda_e}$. Now, find a vector λ such that for every edge $e \in E$, $\mathbb{P}_{\mu_{\lambda}}[e \in T] = x_e(1 \pm \epsilon)$, for some $\epsilon < 2^{-n}$. Such a vector λ can be found using the multiplicative weight update algorithm [Asa+10] or by applying interior point methods [SV12] or the ellipsoid method [Asa+10]. (We note that the multiplicative weight update method can only guarantee $\epsilon < 1/\text{poly}(n)$ in polynomial time.)

Theorem 1.3 ([Asa+10]). Let z be a point in the spanning tree polytope (see (3)) of a graph G = (V, E). For any $\epsilon > 0$, a vector $\lambda : E \to \mathbb{R}_{\geq 0}$ can be found such that the corresponding λ -uniform spanning tree distribution, μ_{λ} , satisfies

$$\sum_{T \in \mathcal{T}: T \ni e} \mathbb{P}_{\mu_{\lambda}}[T] \leq (1 + \varepsilon)z_{e}, \quad \forall e \in E,$$

i.e., the marginals are approximately preserved. In the above \mathcal{T} is the set of all spanning trees of (V, E). The running time is polynomial in n = |V|, $-\log \min_{e \in E} z_e$ and $\log(1/\epsilon)$.

Finally, we sample a tree $T \sim \mu_{\lambda}$ and then add the minimum cost matching on the odd degree vertices of T. The above algorithm is a slight modification of the algorithm proposed in

Algorithm 1 An Improved Approximation Algorithm for TSP

Find an optimum solution x^0 of Eq. (1), and let $e_0 = (u_0, v_0)$ be an edge with $x_{e_0}^0 = 1$, $c(e_0) = 0$. Let $E_0 = E \cup \{e_0\}$ be the support of x^0 and x be x^0 restricted to E and G = (V, E).

Find a vector $\lambda: E \to \mathbb{R}_{\geq 0}$ such that for any $e \in E$, $\mathbb{P}_{\mu_{\lambda}}[e] = x_e(1 \pm 2^{-n})$.

Sample a tree $T \sim \mu_{\lambda}$.

Let *M* be the minimum cost matching on odd degree vertices of *T*.

Output $T \cup M$.

[OSS11]. We refer the interested reader to exciting work of Genova and Williamson [GW17] on the empirical performance of the max-entropy rounding algorithm. We also remark that although the algorithm implemented in [GW17] is slightly different from the above algorithm, we expect the performance to be similar.

1.2 New Techniques

Here we discuss new machinery and technical tools that we developed for this result which could be of independent interest.

1.2.1 Polygon Structure for Near Minimum Cuts Crossed on one Side.

Let G = (V, E, x) be an undirected graph equipped with a weight function $x : E \to \mathbb{R}_{\geq 0}$ such that for any cut (S, \overline{S}) such that $u_0, v_0 \notin S$, $x(\delta(S)) \geq 2$.

For some (small) $\eta \geq 0$, consider the family of η -near min cuts of G. Let C be a connected component of crossing η -near min cuts. Given C we can partition vertices of G into sets a_0, \ldots, a_{m-1} (called atoms); this is the coarsest partition such that for each a_i , and each $(S, \overline{S}) \in C$, we have $a_i \subseteq S$ or $a_i \subseteq \overline{S}$. Here a_0 is the atom that contains u_0, v_0 .

There has been several works studying the structure of edges between these atoms and the structure of cuts in C w.r.t. the a_i 's. The *cactus structure* (see [DKL76]) shows that if $\eta = 0$, then we can arrange the a_i 's around a cycle, say a_1, \ldots, a_m (after renaming), such that $x(E(a_i, a_{i+1})) = 1$ for all i.

Benczúr and Goemans [Ben95; BG08] studied the case when $\eta \le 6/5$ and introduced the notion of *polygon representation*, in which case atoms can be placed on the sides of an equilateral polygon and some atoms placed inside the polygon, such that every cut in \mathcal{C} can be represented by a diagonal of this polygon. Later, [OSS11] studied the structure of edges of G in this polygon when $\eta < 1/100$.

In this paper, we show it suffices to study the structure of edges in a special family of polygon representations: Suppose we have a polygon representation for a connected component $\mathcal C$ of η -near min cuts of G such that

- No atom is mapped inside,
- If we identify each cut $(S, \overline{S}) \in \mathcal{C}$ with the interval along the polygon that does not contain a_0 , then any interval is only crossed on one side (only on the left or only on the right).

Then, we have (i) For any atom a_i , $x(\delta(a_i)) \le 2 + O(\delta)$ and (ii) For any pair of atoms a_i , a_{i+1} , $x(E(a_i, a_{i+1}) \ge 1 - \Omega(\eta)$ (see Theorem 4.9 for details).

We expect to see further applications of our theorem in studying variants of TSP.

1.2.2 Generalized Gurvits' Lemma

Given a real stable polynomial $p \in \mathbb{R}_{\geq 0}[z_1, \dots, z_n]$ (with non-negative coefficients), Gurvits proved the following inequality [Gur06; Gur08]

$$\frac{n!}{n^n}\inf_{z>0}\frac{p(z_1,\ldots,z_n)}{z_1\ldots z_n}\leq \partial_{z_1}\ldots\partial_{z_n}p|_{z=0}\leq \inf_{z>0}\frac{p(z_1,\ldots,z_n)}{z_1\ldots z_n}.$$
 (2)

As an immediate consequence, one can prove the following theorem about strongly Rayleigh (SR) distributions.

Theorem 1.4. Let $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$ be SR and A_1, \ldots, A_m be random variables corresponding to the number of elements sampled in m disjoint subsets of [n] such that $\mathbb{E}[A_i] = n_i$ for all i. If $n_i = 1$ for all $1 \leq i \leq n$, then $\mathbb{P}[\forall i, A_i = 1] \geq \frac{m!}{m^m}$.

One can ask what happens if the vector $\vec{n} = (n_1, \dots, n_m)$ in the above theorem is not equal but close to the all ones vector, **1**.

A related theorem was proved in [OSS11].

Theorem 1.5. Let $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$ be SR and A,B be random variables corresponding to the number of elements sampled in two disjoint sets. If $\mathbb{P}[A+B=2] \geq \epsilon$, $\mathbb{P}[A \leq 1]$, $\mathbb{P}[B \leq 1] \geq \alpha$ and $\mathbb{P}[A \geq 1]$, $\mathbb{P}[B \geq 1] \geq \beta$ then $\mathbb{P}[A=B=1] \geq \epsilon \alpha \beta/3$.

We prove a generalization of both of the above statements; roughly speaking, we show that as long as $\|\vec{n} - \mathbf{1}\|_1 < 1 - \epsilon$ then $\mathbb{P}\left[\forall i, A_i = 1\right] \ge f(\epsilon, m)$ where $f(\epsilon, m)$ has no dependence on n, the number of underlying elements in the support of μ .

Theorem 1.6 (Informal version of Proposition 5.1). Let $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$ be SR and let A_1, \ldots, A_m be random variables corresponding to the number of elements sampled in m disjoint subsets of [n]. Suppose that there are integers n_1, \ldots, n_m such that for any set $S \subseteq [m]$, $\mathbb{P}\left[\sum_{i \in S} A_i = \sum_{i \in S} n_i\right] \geq \epsilon$. Then,

$$\mathbb{P}\left[\forall i, A_i = n_i\right] \geq f(\epsilon, m).$$

The above statement is even stronger than Theorem 1.4 as we only require $\mathbb{P}\left[\sum_{i \in S} A_i = \sum_{i \in S} n_i\right]$ to be bounded away from 0 for any set $S \subseteq [m]$ and we don't need a bound on the expectation. Our proof of the above theorem has double exponential dependence on ϵ . We leave it an open problem to find the optimum dependency on ϵ . Furthermore, our proof of the above theorem is probabilistic in nature; we expect that an algebraic proof based on the theory of real stable polynomials will provide a significantly improved lower bound. Unlike the above theorem, such a proof may possibly extend to the more general class of completely log-concave distributions [AOV18].

1.2.3 Conditioning while Preserving Marginals

Consider a SR distribution $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$ and let $x: [n] \to \mathbb{R}_{\geq 0}$, where for all $i, x_i = \mathbb{P}_{T \sim \mu} [i \in T]$, be the marginals.

Let $A, B \subseteq [n]$ be two disjoint sets such that $\mathbb{E}[A_T]$, $\mathbb{E}[B_T] \approx 1$. It follows from Theorem 1.6 that $\mathbb{P}[A_T = B_T = 1] \ge \Omega(1)$. Here, however, we are interested in a stronger event; let $\nu = \mu | A_T = B_T = 1$ and let $y_i = \mathbb{P}_{T \sim \mu}[i \in T]$. It turns out that the y vector can be very different from the x vector, in particular, for some i's we can have $|y_i - x_i|$ bounded away from 0. We show that there is an event of non-negligible probability that is a subset of $A_T = B_T = 1$ under which the marginals of elements in A, B are almost preserved.

Theorem 1.7 (Informal version of Proposition 5.6). Let $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$ be a SR distribution and let $A, B \subseteq [n]$ be two disjoint subsets such that $\mathbb{E}[A_T]$, $\mathbb{E}[B_T] \approx 1$. For any $\alpha \ll 1$ there is an event $\mathcal{E}_{A,B}$ such that $\mathbb{P}[\mathcal{E}_{A,B}] \geq \Omega(\alpha^2)$ and

- $\mathbb{P}\left[A_T = B_T = 1 | \mathcal{E}_{A,B}\right] = 1$,
- $\sum_{i\in A} |\mathbb{P}[i] \mathbb{P}[i|\mathcal{E}]| \leq \alpha$,
- $\sum_{i \in B} |\mathbb{P}[i] \mathbb{P}[i|\mathcal{E}]| \leq \alpha$.

We remark that the quadratic lower bound on α is necessary in the above theorem for a sufficiently small $\alpha > 0$. The above theorem can be seen as a generalization of Theorem 1.4 in the special case of two sets.

We leave it an open problem to extend the above theorem to arbitrary k disjoint sets. We suspect that in such a case the ideal event $\mathcal{E}_{A_1,\ldots,A_k}$ occurs with probability $\Omega(\alpha)^k$ and preserves all marginals of elements in each of the sets A_1,\ldots,A_k up to a total variation distance of α .

2 Preliminaries

2.1 Notation

We write $[n] := \{1, ..., n\}$ to denote the set of integers from 1 to n. For a set of edges $A \subseteq E$ and (a tree) $T \subseteq E$, we write

$$A_T = |A \cap T|$$
.

For a set $S \subseteq V$, we write

$$E(S) = \{(u, v) \in E : u, v \in S\}$$

to denote the set of edges in *S* and we write

$$\delta(S) = \{(u, v) \in E : |\{u, v\} \cap S| = 1\}$$

to denote the set of edges that leave S. For two *disjoint* sets of vertices $A, B \subseteq V$, we write

$$E(A, B) = \{(u, v) \in E : u \in A, v \in B\}.$$

For a set $A \subseteq E$ and a function $x : E \to \mathbb{R}$ we write

$$x(A) := \sum_{e \in A} x_e$$
.

For two sets $A, B \subseteq V$, we say A crosses B if all of the following sets are non-empty:

$$A \cap B$$
, $A \setminus B$, $B \setminus A$, $\overline{A \cup B}$.

We write G = (V, E, x) to denote an (undirected) graph G together with special vertices u_0, v_0 and a weight function $x : E \to \mathbb{R}_{\geq 0}$ such that

$$x(\delta(S)) \ge 2$$
, $\forall S \subsetneq V : u_0, v_0 \notin S$.

For such a graph, we say a cut $S \subseteq V$ is an η -near min cut w.r.t., x (or simply η -near min cut when x is understood) if $x(\delta(S)) \le 2 + \eta$. Unless otherwise specified, in any statement about a cut (S, \overline{S}) in G, we assume $u_0, v_0 \notin S$.

2.2 Polyhedral Background

For any graph G = (V, E), Edmonds [Edm70] gave the following description for the convex hull of spanning trees of a graph G = (V, E), known as the *spanning tree polytope*.

$$z(E) = |V| - 1$$

$$z(E(S)) \le |S| - 1 \qquad \forall S \subseteq V$$

$$z_e > 0 \qquad \forall e \in E.$$
(3)

Edmonds [Edm70] proved that the extreme point solutions of this polytope are the characteristic vectors of the spanning trees of *G*.

Fact 2.1. Let x^0 be a feasible solution of (1) such that $x^0_{e_0} = 1$ with support $E_0 = E \cup \{e_0\}$. Let x be x^0 restricted to E; then x is in the spanning tree polytope of G = (V, E).

Proof. For any set
$$S \subseteq V$$
 such that $u_0, v_0 \notin S$, $x(E(S)) = \frac{2|S| - x^0(\delta(S))}{2} \le |S| - 1$. If $u_0 \in S$, $v_0 \notin S$, then $x(E(S)) = \frac{2|S| - 1 - (x^0(\delta(S)) - 1)}{2} \le |S| - 1$. Finally, if $u_0, v_0 \in S$, then $x(E(S)) = \frac{2|S| - 2 - x^0(\delta(S))}{2} \le |S| - 2$. The claim follows because $x(E) = x^0(E_0) - 1 = n - 1$. □

Since $c(e_0) = 0$, the following fact is immediate.

Fact 2.2. Let G = (V, E, x) where x is in the spanning tree polytope. Let μ be any distribution of spanning trees with marginals x, then $\mathbb{E}_{T \sim \mu} [c(T \cup e_0)] = c(x)$.

To bound the cost of the min-cost matching on the set O of odd degree vertices of the tree T, we use the following characterization of the O-join polytope² due to Edmonds and Johnson [EJ73].

Proposition 2.3. For any graph G = (V, E), cost function $c : E \to \mathbb{R}_+$, and a set $O \subseteq V$ with an even number of vertices, the minimum weight of an O-join equals the optimum value of the following integral linear program.

Definition 2.4 (Satisfied cuts). For a set $S \subseteq V$ such that $u_0, v_0 \notin S$ and a spanning tree $T \subseteq E$ we say a vector $y : E \to \mathbb{R}_{>0}$ satisfies S if one of the following holds:

- $\delta(S)_T$ is even, or
- $y(\delta(S)) \geq 1$.

To analyze our algorithm, we will see that the main challenge is to construct a (random) vector y that satisfies all cuts and $\mathbb{E}[c(y)] \leq (1/2 - \epsilon)OPT$.

²The standard name for this is the T-join polytope. Because we reserve T to represent our tree, we call this the O-join polytope, where O represents the set of odd vertices in the tree.

2.3 Structure of Near Minimum Cuts

Lemma 2.5 ([OSS11]). For G = (V, E, x), let $A, B \subseteq V$ be two crossing ϵ_A, ϵ_B near min cuts respectively. Then, $A \cap B$, $A \cup B$, $A \setminus B$, $A \setminus B$, $A \cap B$, are $\epsilon_A + \epsilon_B$ near min cuts.

Proof. We prove the lemma only for $A \cap B$; the rest of the cases can be proved similarly. By submodularity,

$$x(\delta(A \cap B)) + x(\delta(A \cup B)) \le x(\delta(A)) + x(\delta(B)) \le 4 + \epsilon_A + \epsilon_B$$

Since $x(\delta(A \cup B)) \ge 2$, we have $x(\delta(A \cap B)) \le 2 + \epsilon_A + \epsilon_B$, as desired.

The following lemma is proved in [Ben97]:

Lemma 2.6 ([Ben97, Lem 5.3.5]). For G = (V, E, x), let $A, B \subsetneq V$ be two crossing ϵ -near minimum cuts. Then,

$$x(E(A \cap B, A - B)), x(E(A \cap B, B - A)), x(E(\overline{A \cup B}, A - B)), x(E(\overline{A \cup B}, B - A)) \ge (1 - \epsilon/2).$$

Lemma 2.7. For G = (V, E, x), let $A, B \subseteq V$ be two ϵ near min cuts such that $A \subseteq B$. Then

$$x(\delta(A) \cap \delta(B)) = x(E(A, \overline{B})) \le 1 + \epsilon$$
, and $x(E(\delta(A) \setminus \delta(B))) \ge 1 - \epsilon/2$.

Proof. Notice

$$2 + \epsilon \ge x(\delta(A)) = x(E(A, B \setminus A)) + x(E(A, \overline{B}))$$

$$2 + \epsilon \ge x(\delta(B)) = x(E(B \setminus A, \overline{B})) + x(E(A, \overline{B}))$$

Summing these up, we get

$$2x(E(A,\overline{B})) + x(E(A,B \setminus A)) + x(E(B \setminus A,\overline{B})) = 2x(E(A,\overline{B})) + x(\delta(B \setminus A)) \le 4 + 2\epsilon.$$

Since $B \setminus A$ is non-empty, $x(\delta(B \setminus A)) \ge 2$, which implies the first inequality. To see the second one, let $C = B \setminus A$ and note

$$4 \le x(\delta(A)) + x(\delta(C)) = 2x(E(A,C)) + x(\delta(B)) \le 2x(E(A,C)) + 2 + \epsilon$$

which implies $x(E(A,C)) \ge 1 - \epsilon/2$.

2.4 Strongly Rayleigh Distributions and λ -uniform Spanning Tree Distributions

Let \mathcal{B}_E be the set of all probability measures on the Boolean algebra 2^E . Let $\mu \in \mathcal{B}_E$. The generating polynomial $g_{\mu} : \mathbb{R}[\{z_e\}_{e \in E}]$ of μ is defined as follows:

$$g_{\mu}(z) := \sum_{S} \mu(S) \prod_{e \in S} z_e.$$

We say μ is a strongly Rayleigh distribution if $g_{\mu} \neq 0$ over all $\{y_e\}_{e \in E} \in \mathbb{C}^E$ where $\mathrm{Im}(z_e) > 0$ for all $e \in E$. We say μ is d-homogenous if for any $\lambda \in \mathbb{R}$, $g_{\mu}(\lambda \mathbf{z}) = \lambda^d g_{\mu}(\mathbf{z})$. Strongly Rayleigh (SR) distributions were defined in [BBL09] where it was shown any λ -uniform spanning tree distribution is strongly Rayleigh. In this subsection we recall several properties of SR distributions proved in [BBL09; OSS11] which will be useful to us.

Closure Operations of SR Distributions. SR distributions are closed under the following operations.

• **Projection.** For any $\mu \in \mathcal{B}_E$, and any $F \subseteq E$, the projection of μ onto F is the measure μ_F where for any $A \subseteq F$,

$$\mu_F(A) = \sum_{S: S \cap F = A} \mu(S).$$

- **Conditioning.** For any $e \in E$, $\{\mu | e \text{ out}\}$ and $\{\mu | e \text{ in}\}$.
- **Truncation.** For any integer $k \ge 0$ and $\mu \in \mathcal{B}_E$, truncation of μ to k, is the measure μ_k where for any $A \subseteq E$,

$$\mu_k(A) = \begin{cases} \frac{\mu(A)}{\sum_{S:|S|=k} \mu(S)} & \text{if } |A| = k \\ 0 & \text{otherwise.} \end{cases}$$

• **Product.** For any two disjoint sets E, F, and $\mu_E \in \mathcal{B}_E$, $\mu_F \in \mathcal{B}_F$ the product measure $\mu_{E \times F}$ is the measure where for any $A \subseteq E$, $B \subseteq F$, $\mu_{E \times F}(A \cup B) = \mu_E(A)\mu_F(B)$.

Throughout this paper we will repeatedly apply the above operations. We remark that SR distributions are *not* necessarily closed under truncation of a subset, i.e., if we require exactly k elements from $F \subsetneq E$.

Since λ -uniform spanning tree distributions are special classes of SR distributions, if we perform any of the above operations on a λ -uniform spanning tree distribution μ we get another SR distribution. Below, we see that by performing the following particular operations we still have a λ -uniform spanning tree distribution (perhaps with a different λ).

Closure Operations of λ -uniform Spanning Tree Distributions

- Conditioning. For any $e \in E$, $\{\mu | e \text{ out}\}$, $\{\mu | e \text{ in}\}$.
- **Tree Conditioning**. For G = (V, E), a spanning tree distribution $\mu \in \mathcal{B}_E$, and $S \subseteq V$, $\{\mu | S \text{ tree}\}$.

Note that arbitrary spanning tree distributions are not necessarily closed under truncation and projection. We remark that SR measures are also closed under an analogue of tree conditioning, i.e., for a set $F \subseteq E$, let $k = \max_{S \in \text{supp } \mu} |S \cap F|$. Then, $\{\mu | |S \cap F| = k\}$ is SR. But if μ is a spanning tree distribution we get an extra *independence* property. The following independence is crucial to several of our proofs.

Fact 2.8. For a graph G = (V, E), and a vector $\lambda(G) : E \to \mathbb{R}_{\geq 0}$, let $\mu_{\lambda(G)}$ be the corresponding λ -uniform spanning tree distribution. Then for any $S \subsetneq V$,

$$\{\mu_{\lambda(G)}|S \ tree\} = \mu_{\lambda(G[S])} \times \mu_{\lambda(G/S)}.$$

Proof. Intuitively, this holds because in the max entropy distribution, conditioned on S being a tree, any tree chosen inside S can be composed with any tree chosen on G/S to obtain a

spanning tree on G. So, to maximize the entropy these trees should be chosen independently. More formally for any $T_1 \in G[S]$ and $T_2 \in G/S$,

$$\mathbb{P}\left[T = T_1 \cup T_2 \mid S \text{ is a tree}\right] = \frac{\lambda^{T_1} \lambda^{T_2}}{\sum_{T_1' \in G[S], T_2' \in G/S} \lambda^{T_1'} \lambda^{T_2'}} \\
= \frac{\lambda^{T_1}}{\sum_{T_1' \in G[S]} \lambda^{T_1'}} \cdot \frac{\lambda^{T_2}}{\sum_{T_2' \in G/S} \lambda^{T_2'}} \\
= \mathbb{P}_{T_1' \sim G[S]} \left[T_1' = T_1\right] \mathbb{P}_{T_2' \sim G/S} \left[T_2' = T_2\right],$$

giving independence.

Negative Dependence Properties. An *upward event*, \mathcal{A} , on 2^E is a collection of subsets of E that is closed under upward containment, i.e. if $A \in \mathcal{A}$ and $A \subseteq B \subseteq E$, then $B \in \mathcal{A}$. Similarly, a *downward event* is closed under downward containment. An *increasing function* $f: 2^E \to \mathbb{R}$, is a function where for any $A \subseteq B \subseteq E$, we have $f(A) \le f(B)$. We also say $f: 2^E \to \mathbb{R}$ is a *decreasing function* if -f is an increasing function. So, an indicator of an upward event is an increasing function. For example, if E is the set of edges of a graph E, then the existence of a Hamiltonian cycle is an increasing function, and the 3-colorability of E is a decreasing function.

Definition 2.9 (Negative Association). *A measure* $\mu \in \mathcal{B}_E$ *is* negatively associated *if for any increasing functions* $f, g: 2^E \to \mathbb{R}$, *that depend on* disjoint *sets of edges,*

$$\mathbb{E}_{u}\left[f\right] \cdot \mathbb{E}_{u}\left[g\right] \geq \mathbb{E}_{u}\left[f \cdot g\right]$$

It is shown in [BBL09; FM92] that strongly Rayleigh measures are negatively associated.

Stochastic Dominance. For two measures $\mu, \nu: 2^E \to \mathbb{R}_{\geq 0}$, we say $\mu \leq \nu$ if there exists a *coupling* $\rho: 2^E \times 2^E \to \mathbb{R}_{\geq 0}$ such that

$$\sum_{B} \rho(A, B) = \mu(A), \forall A \in 2^{E},$$

$$\sum_{A} \rho(A, B) = \nu(B), \forall B \in 2^{E},$$

and for all A, B such that $\rho(A, B) > 0$ we have $A \subseteq B$ (coordinate-wise).

Theorem 2.10 (BBL). If μ is strongly Rayleigh and μ_k , μ_{k+1} are well-defined, then $\mu_k \leq \mu_{k+1}$.

Note that in the above particular case the coupling ρ satisfies the following: For any A, $B \subseteq E$ where $\rho(A, B) > 0$, $B \supseteq A$ and $|B \setminus A| = 1$, i.e., B has exactly one more element.

Let μ be a strongly Rayleigh measure on edges of G. Recall that for a set $A \subseteq E$, we write $A_T = |A \cap T|$ to denote the random variable indicating the number of edges in A chosen in a random sample T of μ . The following facts immediately follow from the negative association and stochastic dominance properties. We will use these facts repeatedly in this paper.

Fact 2.11. Let μ be any SR distribution on E, then for any $F \subset E$, and any integer k

1. (Negative Association) If
$$e \notin F$$
, then $\mathbb{P}_{\mu}\left[e \middle| F_T \geq k\right] \leq \mathbb{P}_{\mu}\left[e\right]$ and $\mathbb{P}_{\mu}\left[e \middle| F_T \leq k\right] \geq \mathbb{P}_{\mu}\left[e\right]$

2. (Stochastic Dominance) If $e \in F$, then $\mathbb{P}_{\mu}[e|F_T \geq k] \geq \mathbb{P}_{\mu}[e]$ and $\mathbb{P}_{\mu}[e|F_T \leq k] \leq \mathbb{P}_{\mu}[e]$.

Fact 2.12. Let μ be a homogenous SR distribution on E. Then,

• (Negative association with homogeneity) For any $A \subseteq E$, and any $B \subseteq \overline{A}$

$$\mathbb{E}_{u}\left[B_{T}|A_{T}=0\right] \leq \mathbb{E}_{u}\left[B_{T}\right] + \mathbb{E}_{u}\left[A_{T}\right] \tag{5}$$

• Suppose that μ is a spanning tree distribution. For $S \subseteq V$, let $q := |S| - 1 - \mathbb{E}_{\mu}[E(S)_T]$. For any $A \subseteq E(S)$, $B \subseteq \overline{E(S)}$,

$$\mathbb{E}_{\mu}\left[B_{T}\right] - q \leq \mathbb{E}_{\mu}\left[B_{T}|S \text{ is a tree}\right] \leq \mathbb{E}_{\mu}\left[B_{T}\right]$$
 (Negative association and homogeneity) $\mathbb{E}_{\mu}\left[A_{T}\right] \leq \mathbb{E}_{\mu}\left[A_{T}|S \text{ is a tree}\right] \leq \mathbb{E}_{\mu}\left[A_{T}\right] + q$ (Stochastic dominance and tree)

Rank Sequence. The rank sequence of μ is the sequence

$$\mathbb{P}[|S|=0]$$
, $\mathbb{P}[|S|=1]$,..., $\mathbb{P}[|S|=m]$,

where $S \sim \mu$. Let $g_{\mu}(\mathbf{z})$ be the generating polynomial of μ . The *diagonal specialization* of μ is the univariate polynomial

$$\bar{g}_{\mu}(z) := g_{\mu}(z,z,\ldots,z).$$

Observe that $\bar{g}(.)$ is the generating polynomial of the rank sequence of μ . It follows that if μ is SR then \bar{g}_{μ} is real rooted.

It is not hard to see that the rank sequence of μ corresponds to sum of independent Bernoullis iff g_{μ} is real rooted. It follows that the rank sequence of an SR distributions has the law of a sum of independent Bernoullis. As a consequence, it follows (see [HLP52; Dar64; BBL09]) that the rank sequence of any strongly Rayleigh measure is log concave (see below for the definition), unimodal, and its mode differs from the mean by less than 1.

Definition 2.13 (Log-concavity [BBL09, Definition 2.8]). A real sequence $\{a_k\}_{k=0}^m$ is log-concave if $a_k^2 \ge a_{k-1} \cdot a_{k+1}$ for all $1 \le k \le m-1$, and it is said to have no internal zeros if the indices of its non-zero terms form an interval (of non-negative integers).

2.5 Sum of Bernoullis

In this section, we collect a number of properties of sums of Bernoulli random variables.

Definition 2.14 (Bernoulli Sum Random Variable). We say BS(q) is a Bernoulli-Sum random variable if it has the law of a sum of independent Bernoulli random variables, say $B_1 + B_2 + ... + B_n$ for some $n \ge 1$, with $\mathbb{E}[B_1 + \cdots + B_n] = q$.

We start with the following theorem of Hoeffding.

Theorem 2.15 ([Hoe56, Corollary 2.1]). Let $g : \{0,1,\ldots,n\} \to \mathbb{R}$ and $0 \le q \le n$ for some integer $n \ge 0$. Let B_1,\ldots,B_n be n independent Bernoulli random variables with success probabilities p_1,\ldots,p_n , where $\sum_{i=1}^n p_i = q$ that minimizes (or maximizes)

$$\mathbb{E}\left[g(B_1+\cdots+B_n)\right]$$

over all such distributions. Then, $p_1, \ldots, p_n \in \{0, x, 1\}$ for some 0 < x < 1. In particular, if only m of p_i 's are nonzero and ℓ of p_i 's are 1, then the rest of the $m - \ell$ are $\frac{q - \ell}{m - \ell}$.

Fact 2.16. Let B_1, \ldots, B_n be independent Bernoulli random variables each with expectation $0 \le p \le 1$. Then

$$\mathbb{P}\left[\sum_{i} B_{i} even\right] = \frac{1}{2}(1 + (1 - 2p)^{n})$$

Proof. Note that

$$(p+(1-p))^n = \sum_{k=0}^n p^k (1-p)^{n-k} \binom{n}{k}$$
 and $((1-p)-p)^n = \sum_{k=0}^n (-p)^k (1-p)^{n-k} \binom{n}{k}$

Summing them up we get,

$$1 + (1 - 2p)^n = \sum_{0 < k < n, k \text{ even}} 2p^k (1 - p)^{n - k} \binom{n}{k}.$$

Corollary 2.17. Given a BS(q) random variable with $0 < q \le 1.2$, then

$$\mathbb{P}\left[BS(q) \ even\right] \le \frac{1}{2}(1 + e^{-2q})$$

Proof. First, if $q \le 1$, then by Hoeffding's theorem we can write BS(q) as sum of n Bernoullis with success probability p = q/n. If n = 1, then the statement obviously holds. Otherwise, by the previous fact, we have (for some n),

$$\mathbb{P}\left[BS(q) \text{ even}\right] \le \frac{1}{2}(1 + (1 - 2p)^n)) \le \frac{1}{2}(1 + e^{-2q})$$

where we used that $|1-2p| \le e^{-2p}$ for $p \le 1/2$.

So, now assume q > 1. Write BS(q) as the sum of n Bernoullis, each with success probabilities 1 or p. First assume we have no ones. Then, either we only have two non-zero Bernoullis with success probability q/2 in which case $\mathbb{P}\left[BS(q) \text{ even}\right] \leq 0.6^2 + 0.4^2$ and we are done. Otherwise, $n \geq 3$ so $p \leq 1/2$ and similar to the previous case we get $\mathbb{P}\left[BS(q) \text{ even}\right] \leq \frac{1}{2}(1 + e^{-2q})$.

Finally, if q > 1 and one of the Bernoullis is always 1, i.e. BS(q) = BS(q-1) + 1, then we get

$$\mathbb{P}\left[BS(q) \text{ even}\right] = \mathbb{P}\left[BS(q-1) \text{ odd}\right] = \frac{1}{2}(1 - (1-2p)^{n-1}) \le \frac{1}{2}(1 - e^{-4(q-1)}) \le 0.3$$

where we used that $1 - x \ge e^{-2x}$ for $0 \le x \le 0.2$.

Lemma 2.18. Let p_0, \ldots, p_n be a log-concave sequence. If for some $i, \gamma p_i \geq p_{i+1}$ for some $\gamma < 1$, then,

$$\begin{split} &\sum_{j=k}^{n} p_{j} \leq \frac{p_{k}}{1-\gamma}, \quad \forall k \geq i \\ &\sum_{j=i+1}^{n} p_{j} \cdot j \leq \frac{p_{i+1}}{1-\gamma} \left(i + 1 + \frac{\gamma}{1-\gamma} \right). \end{split}$$

Proof. Since we have a log-concave sequence we can write

$$\frac{1}{\gamma} \le \frac{p_i}{p_{i+1}} \le \frac{p_{i+1}}{p_{i+2}} \le \dots \tag{6}$$

Since all of the above ratios are at least $1/\gamma$, for all $k \ge 1$ we can write

$$p_{i+k} \leq \gamma^{k-1} p_{i+1} \leq \gamma^k p_i$$

Therefore, the first statement is immediate and the second one follows,

$$\sum_{j=i+1}^{n} p_{j} j \leq \sum_{k=0}^{\infty} \gamma^{k} p_{i+1} (i+k+1) = p_{i+1} \left(\frac{i+1}{1-\gamma} + \frac{\gamma}{(1-\gamma)^{2}} \right)$$

Corollary 2.19. Let X be a BS(q) random variable such that $\mathbb{P}[X = k] \ge 1 - \epsilon$ for some integer $k \ge 1$, $\epsilon < 1/10$. Then, $k(1 - \epsilon) \le q \le k(1 + \epsilon) + 3\epsilon$.

Proof. The left inequality simply follows since $X \ge 0$. Since $\mathbb{P}[X = k + 1] \le \epsilon$, we can apply Lemma 2.18 with $\gamma = \epsilon/(1 - \epsilon)$ to get

$$\mathbb{E}\left[X|X \ge k+1\right] \mathbb{P}\left[X \ge k+1\right] \le \frac{\epsilon(1-\epsilon)}{1-2\epsilon} \left(k+1+\frac{\epsilon}{1-2\epsilon}\right)$$

Therefore,

$$q = \mathbb{E}\left[X\right] \le k(1 - \epsilon) + \frac{\epsilon(1 - \epsilon)}{1 - 2\epsilon}(k + 1 + \frac{\epsilon}{1 - 2\epsilon}) \le k(1 + \epsilon) + 3\epsilon$$

as desired.

Fact 2.20. For integers k < t and $k - 1 \le p \le k$,

$$\prod_{i=1}^{k-1} (1 - i/t)(1 - p/t)^{t-k} \ge e^{-p}.$$

Proof. We show that the LHS is a decreasing function of *t*. Since ln is monotone, it is enough to show

$$0 \ge \partial_t \ln(\text{LHS}) = \partial_t \left(\sum_{i=1}^{k-1} \ln(1 - i/t) + (t - k) \ln(1 - p/t) \right)$$
$$= \frac{1}{t^2} \sum_{i=1}^{k-1} \frac{1}{\frac{1}{i} - \frac{1}{t}} + \ln(1 - p/t) + \frac{(t - k)p}{t(t - p)}$$

Using $\sum_{i=1}^{k-2} \frac{1}{t^2/i-t} \le \int_0^{k-1} \frac{dx}{t^2/x-t} = -(k-1)/t - \ln(1-(k-1)/t)$ it is enough to show

$$0 \ge -\frac{k-1}{t} - \ln(1 - \frac{k-1}{t}) + \ln(1 - p/t) + \frac{(t-k)p}{t(t-p)} + \frac{1}{t^2(\frac{1}{k-1} - \frac{1}{t})}$$
$$= \ln\frac{t-p}{t-k+1} + \frac{p-k}{t-p} + \frac{1}{t} + \frac{k-1}{t(t-k+1)}$$

Rearranging, it is equivalent to show

$$\ln(1 + \frac{p - k + 1}{t - p}) \ge \frac{p - k}{t - p} + \frac{1}{t - k + 1}$$

Since p > k - 1, using taylor series of ln, to prove the above it is enough to show

$$\frac{p-k+1}{t-p} - \frac{(p-k+1)^2}{2(t-p)^2} \ge \frac{p-k}{t-p} + \frac{1}{t-k+1}.$$

This is equivalent to show

$$\frac{p-k+1}{(t-p)(t-k+1)} \ge \frac{(p-k+1)^2}{2(t-p)^2} \Leftrightarrow \frac{1}{t-k+1} \ge \frac{p-k+1}{2(t-p)}$$

Finally the latter holds because $(t - k + 1)(p - k + 1) \le (t - k + 1) \le 2(t - p)$ where we use $t \ge k + 1$ and $p \le k$.

Let $\operatorname{Poi}(p,k) = e^{-p}p^k/k!$ be the probability that a Poisson random variable with rate p is exactly k; similarly, define $\operatorname{Poi}(p, \leq k)$, $\operatorname{Poi}(p, \geq k)$ as the probability that a Poisson with rate p is at most k or at least k.

Lemma 2.21. Let X be a Bernoulli sum BS(p) for some n. For any integer $k \ge 0$ such that k-1 , the following holds true

$$\mathbb{P}\left[X=k\right] \ge \min_{0 \le \ell \le p, k} \operatorname{Poi}(p-\ell, k-\ell) \left(1 - \frac{p-\ell}{k-\ell+1}\right)^{(p-k)_+}$$

where the minimum is over all nonnegative integers $\ell \leq p, k$, and for $z \in \mathbb{R}$, $z_+ = \max\{z, 0\}$.

Proof. Let $X = B_1 + \cdots + B_n$ where B_i is a Bernoulli. Applying Hoeffding's theorem, if ℓ of them have success probability 1, we need to prove a lower bound of $\operatorname{Poi}(p-\ell,k-\ell)(1-\frac{p-\ell}{k-\ell+1})^{(p-k)_+}$. So, assuming none have success probability 1, it follows that each has success probability p/n. If $k \geq p$,

$$\mathbb{P}\left[X = k\right] = \binom{n}{k} \left(\frac{p}{n}\right)^k (1 - p/n)^{n-k} = \prod_{i=1}^{k-1} (1 - i/n) \frac{p^k}{k!} (1 - p/n)^{n-k} \ge \frac{p^k}{k!} e^{-p} = \operatorname{Poi}(p, k),$$

where in the inequality we used Fact 2.20 (also note if n = k the inequality follows from Stirling's formula and that $p \ge k - 1$). If k , then as above

$$\mathbb{P}\left[X=k\right] = \prod_{i=1}^{k-1} (1-i/n) \frac{p^k}{k!} (1-p/n)^{n-p} (1-p/n)^{p-k} \ge \operatorname{Poi}(p,k) (1-p/n)^{p-k},$$

where again we used Fact 2.20.

Note that if we further know $X \ge a$ with probability 1 we can restrict ℓ in the statement to be in the interval $[a, \min(p, k)]$.

Lemma 2.22. Let X be a Bernoulli sum BS(p), where for some integer $k = \lceil p \rceil$, Then,

$$\mathbb{P}\left[X \ge k\right] \ge \min_{0 \le \ell \le p} \operatorname{Poi}(p - \ell, \ge k - \ell)$$

where the minimum is over all non-negative integers $\ell \leq p$.

Proof. Suppose that *X* is a BS(p) with *n* Bernoullis with probabilities p_1, \ldots, p_n . If p - 1 < k - 1 < p, by [Hoe56, Thm 4, (25)],

$$\mathbb{P}\left[X \le k - 1\right] \le \max_{0 \le \ell < p} \sum_{i=0}^{k-1-\ell} \binom{n-\ell}{i} q^{i} (1-q)^{n-\ell-i} \tag{7}$$

where $q = \frac{p-\ell}{n-\ell}$.

If *Y* is a BS(p) with m > n Bernoullis with probabilities q_1, \ldots, q_m , the same upper bound applies of course, with m replacing n. Also, note that

$$\max_{p_1...p_n} \mathbb{P}\left[X \le k - 1\right] \le \max_{q_1,...q_m} \mathbb{P}\left[Y \le k - 1\right]$$

since it is always possible to set $q_i = p_i$ for $i \le n$ and $q_j = 0$ for j > n.

Therefore, the upper bound in (7) obtained by taking the limit as n goes to infinity applies, from which it follows that

$$\mathbb{P}\left[X \le k - 1\right] \le \max_{0 \le \ell < p} \sum_{i=0}^{k-1-\ell} \operatorname{Poi}(p - \ell, i)$$

and therefore

$$\mathbb{P}\left[X \ge k\right] \ge \min_{0 \le \ell < p} \operatorname{Poi}(p - \ell, \ge k - \ell).$$

2.6 Random Spanning Trees

Lemma 2.23. Let G = (V, E, x), and let μ be any distribution over spanning trees with marginals x. For any ϵ -near min cut $S \subseteq V$ (such that none of the endpoints of $e_0 = (u_0, v_0)$ are in S), we have

$$\mathbb{P}_{T \sim \mu} [T \cap E(S) \text{ is tree}] \geq 1 - \epsilon/2.$$

Moreover, if μ is a max-entropy distribution with marginals x, then for any set of edges $A \subseteq E(S)$ and $B \subseteq E \setminus E(S)$,

$$\mathbb{E}\left[A_{T}\right] \leq \mathbb{E}\left[A_{T}|S \text{ is tree}\right] \leq \mathbb{E}\left[A_{T}\right] + \epsilon/2, \mathbb{E}\left[B_{T}\right] - \epsilon/2 \leq \mathbb{E}\left[B_{T}|S \text{ is tree}\right] \leq \mathbb{E}\left[B_{T}\right].$$

Proof. First, observe that

$$\mathbb{E}\left[E(S)_T\right] = x(E(S)) \ge \frac{2|S| - x(\delta(S))}{2} \ge |S| - 1 - \epsilon/2,$$

where we used that since $u_0, v_0 \notin S$, and that for any $v \in S$, $\mathbb{E}[\delta(v)_T)] = x(\delta(v)) = 2$. Let $p_S = \mathbb{P}[S \text{ is tree}]$. Then, we must have

$$|S| - 1 - (1 - p_S) = p_S(|S| - 1) + (1 - p_S)(|S| - 2) \ge \mathbb{E}[E(S)_T] \ge |S| - 1 - \epsilon/2.$$

Therefore, $p_S \ge 1 - \epsilon/2$.

The second part of the claim follows from Fact 2.12.

Corollary 2.24. Let $A, B \subseteq V$ be disjoint sets such that $A, B, A \cup B$ are $\epsilon_A, \epsilon_B, \epsilon_{A \cup B}$ -near minimum cuts w.r.t., x respectively, where none of them contain endpoints of e_0 . Then for any distribution μ of spanning trees on E with marginals x,

$$\mathbb{P}_{T \sim \mu} \left[E(A, B)_T = 1 \right] \ge 1 - (\epsilon_A + \epsilon_B + \epsilon_{A \cup B}) / 2.$$

Proof. By the union bound, with probability at least $1 - (\epsilon_A + \epsilon_B + \epsilon_{A \cup B})/2$, A, B, and $A \cup B$ are trees. But this implies that we must have exactly one edge between A, B.

The following simple fact also holds by the union bound.

Fact 2.25. Let G = (V, E, x) and let μ be a distribution over spanning trees with marginals x. For any set $A \subseteq E$, we have

$$\mathbb{P}_{T \sim \mu} \left[T \cap A = \emptyset \right] \ge 1 - x(A).$$

Lemma 2.26. Let G = (V, E, x), and let μ be a λ -uniform random spanning tree distribution with marginals x. For any edge e = (u, v) and any vertex $w \neq u, v$ we have

$$\mathbb{E}\left[W_T|e \notin T\right] \leq \mathbb{E}\left[W_T\right] + \mathbb{P}\left[w \in P_{u,v}|e \notin T\right] \cdot \mathbb{P}\left[e \in T\right],$$

where $W_T = |T \cap \delta(w)|$ and for a spanning tree T and vertices $u, v \in V$, $P_{u,v}(T)$ is the set of vertices on the path from u to v in T.

Proof. Define $E' = E \setminus \{e\}$. Let $\mu' = \mu|_{E'}$ be μ projected on all edges except e. Define $\mu_i = \mu'_{n-2}$ (corresponding to e in the tree) and $\mu_o = \mu'_{n-1}$ (corresponding to e out of the tree). Observe that any tree T has positive measure in exactly one of these distributions. By Theorem 2.10, $\mu_i \leq \mu_o$ so there exists a coupling $\rho: 2^{E'} \times 2^{E'}$ between them such that for

By Theorem 2.10, $\mu_i \leq \mu_o$ so there exists a coupling $\rho: 2^{E'} \times 2^{E'}$ between them such that for any T_i, T_o such that $\rho(T_i, T_o) > 0$, the tree T_o has exactly one more edge than T_i . Also, observe that T_o is always a spanning tree whereas $T_i \cup \{e\}$ is a spanning tree. The added edge (i.e., the edge in $T_o \setminus T_i$) is always along the unique path from u to v in T_o .

For intuition for the rest of the proof, observe that if w is not on the path from u to v in T_o , then the same set of edges is incident to w in both T_i and T_o . So, if w is almost never on the path from u to v, the distribution of W_T is almost independent of e. On the other hand, whenever w is on the path from u to v, then in the worst case, we may replace e with one of the edges incident to w, so conditioned on e out, W_T increases by at most the probability that e is in the tree.

Say x_e is the marginal of e. Then,

$$\mathbb{E}[W_{T}] = \mathbb{E}[W_{T}|e \notin T] (1 - x_{e}) + \mathbb{E}[W_{T}|e \in T] x_{e}$$

$$= \sum_{T_{i}, T_{o}} \rho(T_{i}, T_{o}) W_{o} (1 - x_{e}) + \sum_{T_{i}, T_{o}} \rho(T_{i}, T_{o}) W_{i} x_{e}$$

$$= \sum_{T_{i}, T_{o}} \rho(T_{i}, T_{o}) ((1 - x_{e}) W_{o} + x_{e} W_{i}), \qquad (8)$$

where we write W_i/W_o instead of W_{T_i}/W_{T_o}

$$\mathbb{E} [W_{T} | e \notin T] = \sum_{T_{i}, T_{o}} \rho(T_{i}, T_{o}) W_{o}$$

$$= \sum_{T_{i}, T_{o}: w \in P_{u,v}(T_{o})} \rho(T_{i}, T_{o}) W_{o} + \sum_{T_{i}, T_{o}: w \notin P_{u,v}(T_{o})} \rho(T_{i}, T_{o}) W_{o}$$

$$\leq \sum_{T_{i}, T_{o}: w \in P_{u,v}(T_{o})} \rho(T_{i}, T_{o}) (x_{e}(W_{i} + 1) + (1 - x_{e}) W_{o})$$

$$+ \sum_{T_{i}, T_{o}: w \notin P_{u,v}(T_{o})} \rho(T_{i}, T_{o}) (x_{e} W_{i} + (1 - x_{e}) W_{o})$$

$$= \mathbb{E} [W_{T}] + \sum_{T_{i}, T_{o}: w \in P_{u,v}(T_{o})} \rho(T_{i}, T_{o}) x_{e}$$

$$= \mathbb{E} [W_{T}] + \sum_{T_{o}: w \in P_{u,v}(T_{o})} \mu_{o}(T_{o}) x_{e}$$

$$= \mathbb{E} [W_{T}] + \mathbb{P} [w \in P_{u,v} | e \text{ out}] \cdot \mathbb{P} [e \text{ in}]$$

where in the inequality we used the following: When $w \notin P_{u,v}(T_o)$ we have $W_i = W_o$ and when $w \in P_{u,v}(T_o)$ we have $W_o \le W_i + 1$. Finally, in the third to last equality we used (8).

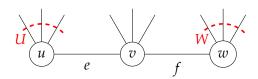

Figure 1: Setting of Lemma 2.27

Lemma 2.27. Let G = (V, E, x), and let μ be a λ -uniform spanning tree distribution with marginals x. For any pair of edges e = (u, v), f = (v, w) such that $|\mathbb{P}[e] - 1/2|$, $|\mathbb{P}[f] - 1/2| < \epsilon$ (see Fig. 1), if $\epsilon < 1/1000$, then

$$\mathbb{E}[W_T|e \notin T] + \mathbb{E}[U_T|f \notin T] \leq \mathbb{E}[W_T + U_T] + 0.81,$$

where $U = \delta(u)_{-e}$ and $W = \delta(w)_{-f}$.

Proof. All probabilistic statements are with respect to ν so we drop the subscript. First, by Lemma 2.26, and negative association we can write,

$$\mathbb{E}\left[W_T|e \notin T\right] \leq \mathbb{E}\left[W_T\right] + \mathbb{P}\left[w \in P_{u,v}|e \notin T\right] \mathbb{P}\left[e \in T\right]$$
$$\leq \mathbb{E}\left[W_T\right] + \mathbb{P}\left[w \in P_{u,v} \land e \notin T\right] + 2\epsilon$$

Note that the lemma only implies $\mathbb{E}\left[\delta(w)_T|e\notin T\right] \leq \mathbb{E}\left[\delta(w)_T\right] + \mathbb{P}\left[w\in P_{u,v}|e\notin T\right]\mathbb{P}\left[e\in T\right]$. To derive the first inequality we also exploit negative association which asserts that the marginal of every edge only goes up under $e\notin T$, so any subset of $\delta(w)$ (in particular W) also goes up by at most $\mathbb{P}\left[e\notin T\land w\in P_{u,v}\right]$. Also, the second inequality uses $\mathbb{P}\left[e\in T\right]\leq \mathbb{P}\left[e\notin T\right]+2\epsilon$. Using a similar inequality for U_T , to prove the lemma it is enough to show that

$$\mathbb{P}\left[w \in P_{u,v} \land e \notin T\right] + \mathbb{P}\left[u \in P_{v,w} \land f \notin T\right] \le 0.808$$

or that when this inequality fails, a different argument yields the lemma.

The main observation is that in any tree it cannot be that both u is on the v-w path and w is on the u-v path. Therefore

$$\mathbb{P}\left[u \in P_{v,w} \mid e, f \notin T\right] + \mathbb{P}\left[w \in P_{u,v} \mid e, f \notin T\right] \leq 1$$

So, we have

$$\mathbb{P}\left[e \notin T \land w \in P_{u,v}\right] + \mathbb{P}\left[f \notin T \land u \in P_{v,w}\right] \\
\leq \mathbb{P}\left[e, f \notin T \land w \in P_{u,v}\right] + \mathbb{P}\left[e \notin T, f \in T\right] + \mathbb{P}_{\nu}\left[e, f \notin T \land u \in P_{v,w}\right] + \mathbb{P}\left[f \notin T, e \in T\right] \\
\leq \mathbb{P}\left[e, f \notin T\right] + \mathbb{P}\left[e \notin T, f \in T\right] + \mathbb{P}\left[f \notin T, e \in T\right] \\
= 1 - \mathbb{P}\left[e, f \in T\right].$$

It remains to upper bound the RHS. Let $\alpha = \mathbb{P}[f \in T | e \notin T]$. Observe that

$$\mathbb{P}\left[e, f \in T\right] = \mathbb{P}\left[f \in T\right] - \mathbb{P}\left[f \in T, e \notin T\right] \ge 1/2 - \epsilon - (1/2 + \epsilon)\alpha.$$

If $\alpha \leq 0.6$, then $\mathbb{P}[e, f \in T] \geq 0.198$ (using $\epsilon < 0.001$) and the claim follows. Otherwise, $\mathbb{P}[f|e \notin T] \geq 0.6$. Similarly, $\mathbb{P}[e|f \notin T] \geq 0.6$. But, by negative association,

$$\mathbb{E}\left[W_{T}|e\notin T\right] \leq \mathbb{E}\left[W_{T}\right] + \mathbb{P}\left[e\right] - \left(\mathbb{P}\left[f|e\notin T\right] - \mathbb{P}\left[f\right]\right) \leq \mathbb{E}\left[W_{T}\right] + 2\epsilon + 0.4 \leq \mathbb{E}\left[W_{T}\right] + 0.405$$

and similarly, $\mathbb{E}[U_T|f \notin T] \leq \mathbb{E}[U_T] + 0.405$, so the claim follows.

3 Overview of Proof

As alluded to earlier, the crux of the proof of Theorem 1.1 is to show that the expected cost of the minimum cost matching on the odd degree vertices of the sampled tree is at most $OPT(1/2 - \epsilon)$. We do this by showing the existence of a cheap feasible O-join solution to (4).

First, recall that if we only wanted to get an O-join solution of value at most OPT/2, to satisfy all cuts, it is enough to set $y_e := x_e/2$ for each edge [Wol80]. To do better, we want to take advantage of the fact that we only need to satisfy a constraint in the O-join for S when $\delta(S)_T$ is odd. Here, we are aided by the fact that the sampled tree is likely to have many even cuts because it is drawn from a Strong Rayleigh distribution.

If an edge e is exclusively on even cuts then y_e can be reduced below $x_e/2$. This, more or less, was the approach in [OSS11] for graphic TSP, where it was shown that a constant fraction of LP edges will be exclusively on even near min cuts with constant probability. The difficulty in implementing this approach in the metric case comes from the fact that a high cost edge can be on many cuts and it may be exceedingly unlikely that all of these cuts will be even simultaneously. Overall, our approach to addressing this is to start with $y_e := x_e/2$ and then modify it with a random³ slack vector $s: E \to \mathbb{R}$: When certain special (few) cuts that e is on are even we let $s_e = -x_e\eta/8$ (for a carefully chosen constant $\eta > 0$); for other cuts that contain e, whenever they are odd, we will increase the slack of other edges on that cut to satisfy them. The bulk of our effort is to show that we can do this while guaranteeing that $\mathbb{E}\left[s_e\right] < -\epsilon\eta x_e$ for some $\epsilon > 0$.

³where the randomness comes from the random sampling of the tree

One thing we do not need to worry about if we perform the reduction just described is any cut S such that $x(\delta(S)) > 2(1 + \eta)$. Since we always have $s_e \ge -x_e \eta/8$, any such cut is always satisfied, even if every edge in $\delta(S)$ is decreased and no edge is increased.

Let OPT be the optimum TSP tour, i.e., a Hamiltonian cycle, with set of edges E^* ; throughout the paper, we write e^* to denote an edge in E^* . To bound the expected cost of the O-join for a random spanning tree $T \sim \mu_{\lambda}$, we also construct a random slack vector $s^* : E^* \to \mathbb{R}_{\geq 0}$ such that $(x + OPT)/4 + s + s^*$ is a feasible for Eq. (4) with probability 1. In Section 3.1 we explain how to use s^* to satisfy all but a linear number of near mincuts.

Theorem 3.1 (Main Technical Theorem). Let x^0 be a solution of LP (1) with support $E_0 = E \cup \{e_0\}$, and x be x^0 restricted to E. Let z := (x + OPT)/2, $\eta \le 10^{-12}$ and let μ be the max-entropy distribution with marginals x. Also, let E^* denote the support of OPT. There are two functions $s: E_0 \to \mathbb{R}$ and $s^*: E^* \to \mathbb{R}_{>0}$ (as functions of $T \sim \mu$), , such that

- i) For each edge $e \in E$, $s_e \ge -x_e \eta/8$.
- ii) For each η -near-min-cut S of z, if $\delta(S)_T$ is odd, then $s(\delta(S)) + s^*(\delta(S)) \ge 0$.
- iii) For every OPT edge e^* , $\mathbb{E}\left[s_{e^*}^*\right] \leq 45\eta^2$ and for every LP edge $e \neq e_0$, $\mathbb{E}\left[s_e\right] \leq -x_e \epsilon_P \eta/2$ for ϵ_P defined in (31).

In the next subsection, we explain the main ideas needed to prove this technical theorem. But first, we show how our main theorem follows readily from Theorem 3.1.

Proof of Theorem 1.1. Let x^0 be an extreme point solution of LP (1), with support E_0 and let x be x^0 restricted to E. By Fact 2.1 x is in spanning tree polytope. Let $\mu = \mu_{\lambda^*}$ be the max entropy distribution with marginals x, and let s, s^* be as defined in Theorem 3.1. We will define $y: E_0 \to \mathbb{R}_{>0}$ and $y^*: E^* \to \mathbb{R}_{>0}$. Let

$$y_e = \begin{cases} x_e/4 + s_e & \text{if } e \in E\\ \infty & \text{if } e = e_0 \end{cases}$$

we also let $y_{e^*}^* = 1/4 + s_{e^*}^*$ for any edge $e^* \in E^*$. We will show that $y + y^*$ is a feasible solution to (4). First, observe that for any S where $e_0 \in \delta(S)$, we have $y(\delta(S)) + y^*(\delta(S)) \ge 1$. Otherwise, we assume $u_0, v_0 \notin S$. If S is an η -near min cut w.r.t., z and $\delta(S)_T$ is odd, then by property (ii) of Theorem 3.1, we have

$$y(\delta(S)) + y^*(\delta(S)) = \frac{z(\delta(S))}{2} + s(\delta(S)) + s^*(\delta(S)) \ge 1.$$

On the other hand, if S is not an η -near min cut (w.r.t., z),

$$\begin{split} y(\delta(S)) + y^*(\delta(S)) &\geq \frac{z(\delta(S))}{2} - \frac{\eta}{8}x(\delta(S)) \\ &\geq \frac{z(\delta(S))}{2} - \frac{\eta}{8}2(z(\delta(S)) - 1) \\ &\geq z(\delta(S))(1/2 - \eta/4) + \eta/4 \geq (2 + \eta)(1/2 - \eta/4) + \eta/4 \geq 1. \end{split}$$

⁴Recall that we merely need to prove the *existence* of a cheap O-join solution. The actual optimal O-join solution can be found in polynomial time.

where in the first inequality we used property (i) of Theorem 3.1 which says that $s_e \ge x_e \eta/8$ with probability 1 for all LP edges and that $s_{e^*}^* \ge 0$ with probability 1. In the second inequality we used that z = (x + OPT)/2, so, since $OPT \ge 2$ across any cut, $x(\delta(S)) \le 2(z(\delta(S)) - 1)$. Therefore, $y + y^*$ is a feasible O-join solution.

Finally, using $c(e_0) = 0$ and part (iii) of Theorem 3.1,

$$\mathbb{E}[c(y) + c(y^*)] = OPT/4 + c(x)/4 + \mathbb{E}[c(s) + c(s^*)]$$

$$< OPT/4 + c(x)/4 + 45\eta^2 OPT - \epsilon_P \eta c(x)/2 < (1/2 - \epsilon_P \eta/4) OPT$$

choosing η such that $45\eta = \epsilon_P/4.1$ and that $c(x) \leq OPT$.

Now, we are ready to bound approximation factor of our algorithm. First, since x^0 is an extreme point solution of (1), $\min_{e \in E_0} x_e^0 \ge \frac{1}{n!}$. So, by Theorem 1.3, in polynomial time we can find $\lambda : E \to \mathbb{R}_{\ge 0}$ such that for any $e \in E$, $\mathbb{P}_{\mu_{\lambda}}[e] \le x_e(1+\delta)$ for some δ that we fix later. It follows that

$$\sum_{e \in E} |\mathbb{P}_{\mu}[e] - \mathbb{P}_{\mu_{\lambda}}[e]| \le n\delta.$$

By stability of maximum entropy distributions (see [SV19, Thm 4] and references therein), we have that $\|\mu - \mu_{\lambda}\|_{1} \leq O(n^{4}\delta) =: q$. Therefore, for some $\delta \ll n^{-4}$ we get $\|\mu - \mu_{\lambda}\|_{1} = q \leq \frac{\varepsilon_{P}\eta}{100}$. That means that

$$\mathbb{E}_{T \sim \mu_{\lambda}}\left[\text{min cost matching}\right] \leq \mathbb{E}_{T \sim \mu}\left[c(y) + c(y^*)\right] + q(OPT/2) \leq \left(\frac{1}{2} - \frac{\epsilon_P \eta}{4} + \frac{\epsilon_P \eta}{100}\right)OPT,$$

where we used that for any spanning tree the cost of the minimum cost matching on odd degree vertices is at most OPT/2. Finally, since $\mathbb{E}_{T \sim \mu_{\lambda}} [c(T)] \leq OPT(1+\delta)$ and $\epsilon_P = 3.9 \cdot 10^{-17}$ we get a $3/2 - 2 \cdot 10^{-36}$ approximation algorithm for TSP.

3.1 Ideas underlying proof of Theorem 3.1

The first step of the proof is to show that it suffices to construct a slack vector s for a "cactus-like" structure of near min-cuts that we call a *hierarchy*. Informally, a hierarchy \mathcal{H} is a laminar family of mincuts⁵, consisting of two types of cuts: *triangle cuts* and *degree cuts*. A triangle S is the union of two min-cuts S and S in S such that S such

We will refer to the set of edges $E(X, \overline{S})$ (resp. $E(Y, \overline{S})$) as A (respectively B) for a triangle cut S. In addition, we say a triangle cut S is *happy* if A_T and B_T are both odd. All other cuts are called degree cuts. A degree cut S is *happy* if S(S) is even.

Theorem 3.2 (Main Payment Theorem (informal)). Let G = (V, E, x) for LP solution x and let μ be the max-entropy distribution with marginals x. Given a hierarchy \mathcal{H} , there is a slack vector $s : E \to \mathbb{R}$ such that

- i) For each edge $e \in E$, $s_e \ge -x_e \eta/8$.
- ii) For each cut $S \in \mathcal{H}$ if $\delta(S)_T$ is not happy, then $s(\delta(S)) \geq 0$.
- iii) For every LP edge $e \neq e_0$, $\mathbb{E}[s_e] \leq -\eta \epsilon_P x_e$ for $\epsilon_P > 0$.

⁵This is really a family of near-min-cuts, but for the purpose of this overview, assume $\eta = 0$

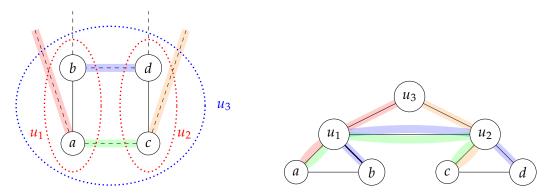

Figure 2: An example of part of a hierarchy with three triangles. The graph on the left shows part of a feasible LP solution where dashed (and sometimes colored) edges have fraction 1/2 and solid edges have fraction 1. The dotted ellipses on the left show the min-cuts u_1, u_2, u_3 in the graph. (Each vertex is also a min-cut). On the right is a representation of the corresponding hierarchy. Triangle u_1 corresponds to the cut $\{a,b\}$, u_2 corresponds to $\{c,d\}$ and u_3 corresponds to $\{a,b,c,d\}$. Note that, for example, the edge (a,c), represented in green, is in $\delta(u_1)$, $\delta(u_3)$, and inside u_3 . For triangle u_1 , we have $A = \delta(a) \setminus (a,b)$ and $B = \delta(b) \setminus (b,d)$.

In the following subsection, we discuss how to prove this theorem. Here we explain at a high level how to define the hierarchy and reduce Theorem 3.1 to this theorem. The details are in Section 4.

First, observe that, given Theorem 3.2, cuts in \mathcal{H} will automatically satisfy (ii) of Theorem 3.1. The approach we take to satisfying all other cuts is to introduce additional slack, the vector s^* , on OPT edges.

Consider the set of all near-min-cuts of z, where z := (x + OPT)/2. Starting with z rather than x allows us to restrict attention to a significantly *more structured* collection of near-min-cuts. The key observation here is that in OPT, all min-cuts have value 2, and any non-min-cut has value at least 4. Therefore averaging x with OPT guarantees that every η -near min-cut of z must consist of a *contiguous sequence of vertices* (an interval) along the OPT cycle. Moreover, each of these cuts is a 2η -near min-cut of x. Arranging the vertices in the OPT cycle around a circle, we identify every such cut with the interval of vertices that does not contain (u_0, v_0) . Also, we say that a cut is crossed on both sides if it is crossed on the left and on the right.

To ensure that any cut S that is *crossed on both sides* is satisfied, we first observe that S is odd with probability $O(\eta)$. To see this, let S_L and S_R be the cuts crossing S on the left and right with minimum intersection with S and consider the two (bad) events $\{E(S \cap S_L, S_L \setminus S)\}_T \neq 1\}$ and $\{E(S \cap S_R, S_R \setminus S)\}_T \neq 1\}$. Recall that if A, B and $A \cup B$ are all near-min-cuts, then $\mathbb{P}[E(A, B)_T \neq 1] = O(\eta)$ (see Corollary 2.24). Applying this fact to the two aforementioned bad events implies that each of them has probability $O(\eta)$. Therefore, we will let the two OPT edges in S(S) be responsible for these two events, i.e., we will increase the slack S^* on these two S(S) edges by S(S) when the respective bad events happens. This gives $\mathbb{E}[S^*(e^*)] = O(\eta^2)$ for each S(S) of S(S) or each open satisfying to S(S) or equal to worry about satisfying to S(S).

Next, we consider the set of near-min-cuts of *z* that are crossed on at most one side. Partition these into maximal connected components of crossing cuts. Each such component corresponds

to an interval along the OPT cycle and, by definition, these intervals form a laminar family.

A single connected component C of at least two crossing cuts is called a *polygon*. We prove the following structural theorem about the polygons induced by z:

Theorem 3.3 (Polygons look like cycles (Informal version of Theorem 4.9)). Given a connected component C of near-min-cuts of z that are crossed on one side, consider the coarsest partition of vertices of the OPT cycle into a sequence a_1, \ldots, a_{m-1} of sets called atoms (together with a_0 which is the set of vertices not contained in any cut of C). Then

- Every cut in C is the union of some number of consecutive atoms in a_1, \ldots, a_{m-1} .
- For each i such that $0 \le i < m-1$, $x(E(a_i, a_{i+1})) \approx 1$ and similarly $x(E(a_{m-1}, a_0)) \approx 1$.
- For each i > 0, $x(\delta(a_i)) \approx 2$.

The main observation used to prove Theorem 3.3 is that the cuts in \mathcal{C} crossed on one side can be partitioned into two laminar families \mathcal{L} and \mathcal{R} , where \mathcal{L} (resp. \mathcal{R}) is the set of cuts crossed on the left (resp. right). This immediately implies that $|\mathcal{C}|$ is linear in m. Since cuts in \mathcal{L} cannot cross each other (and similarly for \mathcal{R}), the proof boils down to understanding the interaction between \mathcal{L} and \mathcal{R} .

The approximations in Theorem 3.3 are correct up to $O(\eta)$. Using additional slack in OPT, at the cost of an additional $O(\eta^2)$ for edge, we can treat these approximate equations as if they are exact. Observe that if $x(E(a_i,a_{i+1}))=1$, and $x(\delta(a_i))=x(\delta(a_{i+1}))=2$ for $1 \le i \le m-2$, then with probability 1, $E(a_i,a_{i+1})_T=1$. Therefore, any cut in $\mathcal C$ which doesn't include a_1 or a_{m-1} is even with probability 1. The cuts in $\mathcal C$ that contain a_1 are even precisely when $E(a_0,a_1)_T=1$ and similarly the cuts in $\mathcal C$ that contain a_{m-1} are even when $E(a_0,a_{m-1})_T=1$. These observations are what allow us to imagine that each polygon is a triangle, i.e., assume m=3.

The hierarchy \mathcal{H} is the set of all η -near mincuts of z that are not crossed at all (these will be the degree cuts), together with a triangle for every polygon. In particular, for a connected component \mathcal{C} of size more than 1, the corresponding triangle cut is $a_1 \cup \ldots \cup a_{m-1}$, with $A = E(a_0, a_1)$ and $B = E(a_0, a_{m-1})$. Observe that from the discussion above, when a triangle cut is happy, then all of the cuts in the corresponding polygon \mathcal{C} are even.

Summarizing, we show that if we can construct a good slack vector s for a hierarchy of degree cuts and triangles, then there is a nonnegative slack vector s^* , that satisfies all near-minimum cuts of z not represented in the hierarchy, while maintaining slack for each OPT edge e^* such that $\mathbb{E}\left[s^*(e^*)\right] = O(\eta^2)$.

Remarks: The reduction that we sketched above only uses the fact that μ is an arbitrary distribution of spanning trees with marginals x and not necessarily a maximum-entropy distribution.

We also observe that to prove Theorem 1.1, we crucially used that $45\eta \ll \varepsilon$. This forces us to take η very small, which is why we get only a "very slightly" improved approximation algorithm for TSP. Furthermore, since we use OPT edges in our construction, we don't get a new upper bound on the integrality gap. We leave it as an open problem to find a reduction to the "cactus" case that doesn't involve using a slack vector for OPT (or a completely different approach).

⁶Roughly, this corresponds to the definition of the polygon being left-happy.

3.2 Proof ideas for Theorem 3.2

We now address the problem of constructing a good slack vector s for a hierarchy of degree cuts and triangle cuts. For each LP edge f, consider the lowest cut in the hierarchy, that contains both endpoints of f. We call this cut p(f). If p(f) is a degree cut, then we call f a top edge and otherwise, it is a bottom edge⁷. We will see that bottom edges are easier to deal with, so we start by discussing the slack vector s for top edges.

Let *S* be a degree cut and let $\mathbf{e} = (u, v)$ (where *u* and *v* are children of *S* in \mathcal{H}) be the set of all top edges f = (u', v') such that $u' \in u$ and $v' \in v$. We call \mathbf{e} a *top edge bundle* and say that *u* and *v* are the *top cuts* of each $f \in \mathbf{e}$. We will also sometimes say that $\mathbf{e} \in S$.

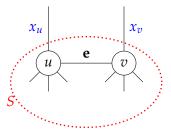

Ideally, our plan is to reduce the slack of every edge $f \in \mathbf{e}$ when it is *happy*, that is, both of its top cuts are even in T. Specifically, we will set $s_f := -\eta x_f$ when $\delta(u)_T$ and $\delta(v)_T$ are even. When this happens, we say that f is *reduced*, and refer to the event $\{\delta(u)_T, \delta(v)_T \text{ even}\}$ as the *reduction* event for f. Since this latter event doesn't depend on the actual endpoints of f, we view this as a simultaneous reduction of $s_{\mathbf{e}}$.

Now consider the situation from the perspective of the degree cut u (where p(u) = S) and consider any incident edge bundle in S, e.g., $\mathbf{e} = (u, v)$. Either its top cuts are both even and $s_{\mathbf{e}} := -\eta x_{\mathbf{e}}$, or they aren't even, because, for example, $\delta(u)_T$ is odd. In this latter situation, edges in $\delta^{\uparrow}(u) := \delta(u) \cap \delta(S)$ might have been reduced (because *their* top two cuts are even), which a priori could leave $\delta(u)$ unsatisfied. In such a case, we *increase* $s_{\mathbf{e}}$ for edge bundles in $\delta^{\rightarrow}(u) := \delta(u) \setminus \delta(S)$ to compensate for this reduction. Our main goal is then to prove is that for any edge bundle its expected reduction is greater than its expected increase. The next example shows this analysis in an ideal setting.

Example 3.4 (Simple case). Fix a top edge bundle $\mathbf{e} = (u,v)$ with $p(\mathbf{e}) = S$. Let $x_u := x(\delta^{\uparrow}(u))$ and let $x_v := x(\delta^{\uparrow}(v))$. Suppose we have constructed a (fractional) *matching* between edges whose top two cuts are children of S in \mathcal{H} and the edges in $\delta(S)$, and this matching satisfies the following three conditions: (a) $\mathbf{e} = (u,v) \in S$ is matched (only) to edges going higher from its top two cuts (i.e., to edges in $\delta^{\uparrow}(u)$ and $\delta^{\uparrow}(v)$), (b) \mathbf{e} is matched to an $m_{\mathbf{e},v}$ fraction of every edge in $\delta^{\uparrow}(u)$ and to an $m_{\mathbf{e},v}$ fraction of each edge in $\delta^{\uparrow}(v)$, where

$$m_{e,u} + m_{e,v} = x_{e}$$

and (c) the fractional value of edges in $\delta^{\rightarrow}(u) := \delta(u) \setminus \delta^{\uparrow}(u)$ matched to edges in $\delta^{\uparrow}(u)$ is equal to x_u . That is, for each $u \in S$, $\sum_{\mathbf{f} \in \delta^{\rightarrow}(u)} m_{\mathbf{f},u} = x_u$.

The plan is for $\mathbf{e} \in S$ to be tasked with part of the responsibility for *fixing the cuts* $\delta(u)$ and $\delta(v)$ when they are odd and edges going higher are reduced. Specifically, $s_{\mathbf{e}}$ is increased to

⁷For example, in Fig. 2, $p(a,c) = u_3$, and (a,c) is a bottom edge.

compensate for an $m_{\mathbf{e},u}$ fraction of the reductions in edges in $\delta^{\uparrow}(u)$ when $\delta(u)_T$ is odd. (And similarly for reductions in v.) Thus,

$$\mathbb{E}\left[s_{\mathbf{e}}\right] = -\mathbb{P}\left[\mathbf{e} \text{ reduced}\right] \eta x_{\mathbf{e}} + m_{\mathbf{e},u} \sum_{g \in \delta^{\uparrow}(u)} \mathbb{P}\left[\delta(u)_{T} \text{ odd}|g \text{ reduced}\right] \mathbb{P}\left[g \text{ reduced}\right] \eta \frac{x_{g}}{x(\delta^{\uparrow}(u))} + m_{\mathbf{e},v} \sum_{g \in \delta^{\uparrow}(v)} \mathbb{P}\left[\delta(v)_{T} \text{ odd}|g \text{ reduced}\right] \mathbb{P}\left[g \text{ reduced}\right] \eta \frac{x_{g}}{x(\delta^{\uparrow}(v))}$$

$$(9)$$

We will lower bound $\mathbb{P}\left[\delta(u)_T \text{ even} | g \text{ reduced}\right]$. We can write this as

$$\mathbb{P}\left[\delta^{\rightarrow}(u)_T \text{ and } \delta^{\uparrow}(u)_T \text{ have same parity } | g \text{ reduced} \right].$$

Unfortunately, we do not currently have a good handle on the parity of $\delta^{\uparrow}(u)_T$ conditioned on g reduced. However, we can use the following simple but crucial property: Since $x(\delta(S)) = 2$, by Lemma 2.23, T consists of two independent trees, one on S and one on $V \setminus S$, each with the corresponding marginals of x. Therefore, we can write

$$\mathbb{P}\left[\delta(u)_T \text{ even} | g \text{ reduced}\right] \ge \min(\mathbb{P}\left[(\delta^{\to}(u))_T \text{ even}\right], \mathbb{P}\left[(\delta^{\to}(u))_T \text{ odd}\right]).$$

This gives us a reasonable bound when $\epsilon \le x_u, x_v \le 1 - \epsilon$ since, because $x(\delta(u)) = x(\delta(v)) = 2$, by the SR property, $(\delta^{\rightarrow}(u))_T$ (and similarly $(\delta^{\rightarrow}(v))_T$) is the sum of Bernoulis with expectation in $[1 + \epsilon, 2 - \epsilon]$. From this it follows that

$$\min(\mathbb{P}\left[(\delta^{\rightarrow}(u))_T \text{ even}\right], \mathbb{P}\left[(\delta^{\rightarrow}(u))_T \text{ odd}\right]) = \Omega(\epsilon).$$

We can therefore conclude that $\mathbb{P}\left[\delta(u)_T \text{ odd} | g \text{ reduced}\right] \leq 1 - O(\epsilon)$.

The rest of the analysis of this special case follows from (a) the fact that our construction will guarantee that for *all* edges g, the probability that g is reduced is *exactly* p, i.e., it is the same for all edges, and (b) the fact that $m_{\mathbf{e},u}x_u + m_{\mathbf{e},v}x_v = x_{\mathbf{e}}$. Plugging these facts back into (9), gives

$$\mathbb{E}\left[s_{\mathbf{e}}\right] \leq -p\eta x_{\mathbf{e}} + m_{\mathbf{e},u}(1-\epsilon)p\eta + m_{\mathbf{e},v}(1-\epsilon)p\eta \leq -p\eta x_{\mathbf{e}} + (1-\epsilon)p\eta x_{\mathbf{e}} = -\epsilon p\eta x_{\mathbf{e}}.$$
(10)

If we could prove (10) for *every* edge f in the support of x, that would complete the proof that the expected cost of the min O-join for a random spanning tree $T \sim \mu$ is at most $(1/2 - \epsilon)OPT$.

Remark: Throughout this paper, we repeatedly use a mild generalization of the above "independent trees fact": that if S is a cut with $x(\delta(S)) \leq 2 + \epsilon$, then S_T is very likely to be a tree. Conditioned on this fact, marginals inside S and outside S are nearly preserved and the trees inside S and outside S are sampled independently (see Lemma 2.23).

Ideal reduction: In the example, we were able to show that $\mathbb{P}\left[\delta(u)_T \text{ odd} \middle| g \text{ reduced}\right]$ was bounded away from 1 for every edge $g \in \delta^{\uparrow}(u)$, and this is how we proved that the expected reduction for each edge was greater than the expected increase on each edge, yielding negative expected slack.

This motivates the following definition: A reduction for an edge g is k-ideal if, conditioned on g reduced, every cut S that is in the top k levels of cuts containing g is odd with probability that is bounded away from 1.

Moving away from an idealized setting: In Example 3.4, we oversimplified in four ways:

- (a) We assumed that it would be possible to show that each top edge is *good*. That is, that its top two cuts are even *simultaneously* with constant probability.
- (b) We considered only top edge bundles (i.e., edges whose top cuts were inside a degree cut).
- (c) We assumed that $x_u, x_v \in [\epsilon, 1 \epsilon]$.
- (d) We assumed the existence of a nice matching between edges whose top two cuts were children of S and the edges in $\delta(S)$.

Our proof needs to address all four anomalies that result from deviating from these assumptions.

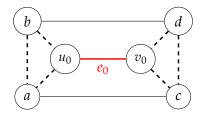

Figure 3: An Example with Bad Edges. A feasible solution of (1) is shown; dashed edges have fraction 1/2 and solid edges have fraction 1. Writing $E = E_0 \setminus \{e_0\}$ as a maximum entropy distribution μ we get the following: Edges (a,b), (c,d) must be completely negatively correlated (and independent of all other edges). So, (b,u_0) , (a,u_0) are also completely negatively correlated. This implies (a,b) is a bad edge.

Bad edges. Consider first (a). Unfortunately, it is not the case that all top edges are good. Indeed, some are *bad*. However, it turns out that bad edges are rare in the following senses: First, for an edge to be bad, it must be a half edge, where we say that an edge \mathbf{e} is a half edge if $x_{\mathbf{e}} \in 1/2 \pm \epsilon_{1/2}$ for a suitably chosen constant $\epsilon_{1/2}$. Second, of any two half edge bundles sharing a common endpoint in the hierarchy, at least one is good. For example, in Fig. 3, (a, u_0) and (b, u_0) are good half-edge bundles. We advise the reader to ignore half edges in the first reading of the paper. Correspondingly, we note that our proofs would be much simpler if half-edge bundles never showed up in the hierarchy. It may not be a coincidence that half edges are hard to deal with, as it is conjectured that TSP instances with half-integral LP solutions are the hardest to round [SWZ12; SWZ13].

Our solution is to *never* reduce bad edges. But this in turn poses two problems. First, it means that we need to address the possibility that the bad edges constitute most of the cost of the LP solution. Second, our objective is to get negative expected slack on each good edge and non-positive expected slack on bad edges. Therefore, if we never reduce bad edges, we can't increase them either, which means that the responsibility for fixing an odd cut with reduced edges going higher will have to be split amongst fewer edges (the incident good ones).

We deal with the first problem by showing that in every cut u in the hierarchy at least 3/4 of the fractional mass in $\delta(u)$ is good and these edges suffice to compensate for reductions on the edges going higher. Moreover, because there are sufficiently many good edges incident to each cut, we can show that either using the slack vector $\{s_e\}$ gives us a low-cost O-join, or we can

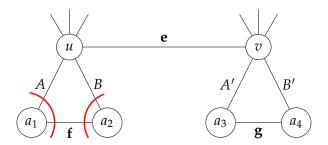

Figure 4: In the triangle u corresponding to the cut $\delta(a_1 \cup a_2)$, when A_T and B_T are odd, all 3 cuts $(\delta(a_1)_T, \delta(a_2)_T)$ and $\delta(a_1 \cup a_2)_T = \delta(u)_T$ are odd (since \mathbf{f}_T is always 1). (Recall also that the edges in the bundle \mathbf{e} must have one endpoint in $\{a_1 \cup a_2\}$ and one endpoint in $\{a_3 \cup a_4\}$, as was the case, e.g., for the edge (a, c) in Fig. 2.)

average it out with another O-join solution concentrated on bad edges to obtain a reduced cost matching of odd degree vertices.

We deal with the second problem by proving Lemma 6.2, which guarantees a matching between *good* edge bundles $\mathbf{e}=(u,v)$ and fractions $m_{\mathbf{e},u},m_{\mathbf{e},v}$ of edges in $\delta^{\uparrow}(u),\delta^{\uparrow}(v)$ such that, roughly, $m_{\mathbf{e},u}+m_{\mathbf{e},v}=(1+O(\epsilon_{1/2}))x_{\mathbf{e}}$.

Dealing with triangles. Turning to (b), consider a triangle cut S, for example $\delta(a_1 \cup a_2)$ in Fig. 4. Recall that in a triangle, we can assume that there is an edge of fractional value 1 connecting a_1 and a_2 in the tree, and this is why we defined the cut to be happy when A_T and B_T are odd: this guarantees that all 3 cuts defined by the triangle $(\delta(a_1), \delta(a_2), \delta(a_1 \cup a_2))$ are even.

Now suppose that $\mathbf{e} = (u, v)$ is a top edge bundle, where u and v are both triangles, as shown in Fig. 4. Then we'd like to reduce $s_{\mathbf{e}}$ when both cuts u and v are happy. But this would require more than simply both cuts being even. This would require all of A_T, B_T, A_T', B_T' to be odd. Note that if, for whatever reason, \mathbf{e} is reduced only when $\delta(u_1)_T$ and $\delta(u_2)_T$ are both even, then it could be, for example, that this only happens when A_T and B_T are both even. In this case, both $\delta(a_1)_T$ and $\delta(a_2)_T$ will be odd with probability 1 (recalling that $\mathbf{f}_T = 1$), which would then necessitate an increase in $s_{\mathbf{f}}$ whenever \mathbf{e} is reduced. In other words, the reduction will not even be 1-ideal.

It turns out to be easier for us to get a 1-ideal reduction rule for **e** as follows: Say that **e** is 2-1-1 happy with respect to u if $\delta(u)_T$ is even and both A'_T , B'_T are odd. We reduce **e** with probability p/2 when it is 2-1-1 happy with respect to u and with probability p/2 when it is 2-1-1 happy with respect to v. This means that when **e** is reduced, half of the time no increase in s_f is needed since u is happy. Similarly for v.

The 2-1-1 criterion for reduction introduces a new kind of bad edge: a half edge that is good, but not 2-1-1 good. We are able to show that non-half-edge bundles are 2-1-1 good (Lemmas 5.22 and 5.23), and that if there are two half edges which are both in A or are both in B, then at least one of them is 2-1-1 good (Lemma 5.25). Finally, we show that if there are two half edges, where one is in A and the other is in B, and neither is 2-1-1 good, then we can apply a different reduction criterion that we call 2-2-2 *good*. When the latter applies, we are guaranteed to decrease both of the half edge bundles simultaneously. All together, the various considerations discussed in this paragraph force us to come up with a relatively more complicated set of rules under which we reduce $s_{\bf e}$ for a top edge bundle ${\bf e}$ whose children are triangle cuts. Section 5 focuses

on developing the relevant probabilistic statements.

Bottom edge reduction. Next, consider a bottom edge bundle $\mathbf{f} = (a_1, a_2)$ where $p(a_1) = p(a_2)$ is a triangle. Our plan is to reduce $s_{\mathbf{f}}$ (i.e., set it to $-\eta x_{\mathbf{f}}$) when the triangle is happy, that is, $A_T = B_T = 1$. The good news here is that every triangle is happy with constant probability. However, when a triangle is *not* happy, $s_{\mathbf{f}}$ may need to increase to make sure that the O-join constraint for $\delta(a_1)$ and $\delta(a_2)$ are satisfied, if edges in A and B going higher are reduced. Since $x_{\mathbf{f}} = x(A) = x(B) = 1$, this means that \mathbf{f} may need to compensate at *twice* the rate at which it is getting reduced. This would result in $\mathbb{E}\left[s_{\mathbf{f}}\right] > 0$, which is the opposite of what we seek.

We use two key ideas to address this problem. First, we reduce top edges and bottom edges by different amounts: Specifically, when the relevant reduction event occurs, we reduce a bottom edge **f** by $\beta x_{\mathbf{f}}$ and top edges **e** by $\tau x_{\mathbf{e}}$, where $\beta > \tau$ (and τ is a multiple of η).

Thus, the expected reduction in s_f is $p\beta x_f = p\beta$, whereas the expected increase (due to compensation of, say, top edges going higher) is $p\tau(x(A) + x(B))q = p\tau 2q$, where

$$q = \mathbb{P}[\text{ triangle happy}|\text{reductions in } A \text{ and } B].$$

Thus, so long as $2\tau q < \beta - \epsilon$, we get the expected reduction in s_f that we seek.

The discussion so far suggests that we need to take τ smaller than $\beta/2q$, which is $\beta/2$ if q is 1, for example. On the other hand, if $\tau = \beta/2$, then when a top edge needs to fix a cut due to reductions on bottom edges, we have the opposite problem – their expected increase will be greater than their expected reduction, and we are back to square one.

Coming to our aid is the second key idea, already discussed in Section 1.2.3. We reduce bottom edges only when $A_T = B_T = 1$ and the marginals of edges in A, B are approximately preserved (conditioned on $A_T = B_T = 1$). This allows us to get much stronger upper bounds on the probability that a lower cut a bottom edge is on is odd, given that the bottom edge is reduced, and enables us to show that bottom edge reduction is ∞ -ideal.

It turns out that the combined effects of (a) choosing $\tau = 0.571\beta$, and (b) getting better bounds on the probability that a lower cut is even given that a bottom edge is reduced, suffice to deal with the interaction between the reductions and the increases in slack for top and bottom edges.

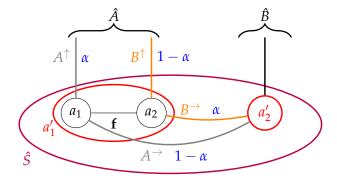

Figure 5: Setting of Example 3.5. Note that the set $A = \delta(a_1) \cap \delta(a'_1)$ decomposes into two sets of edges, A^{\uparrow} , those that are also in $\delta(S)$, and the rest, which we call A^{\rightarrow} . Similarly for B.

Example 3.5. [Bottom-bottom case] To see how preserving marginals helps us handle the interaction between bottom edges at consecutive levels, consider a triangle cut $a'_1 = \{a_1, a_2\}$ whose

parent cut $\hat{S} = \{a'_1, a'_2\}$ is also a triangle cut (as shown in Fig. 5). Let's analyze $\mathbb{E}[s_f]$ where $\mathbf{f} = (a_1, a_2)$. Observe first that $A^{\to} \cup B^{\to}$ is a bottom edge bundle in the triangle \hat{S} and all edges in this bundle are reduced simultaneously when $\hat{A}_T = \hat{B}_T = 1$ and marginals of all edges in $\hat{A} \cup \hat{B}$ are approximately preserved. (For the purposes of this overview, we'll assume they are preserved exactly). Let $x(A^{\uparrow}) = \alpha$. Then since $A = A^{\uparrow} \cup A^{\to}$ and x(A) = 1, we have $x(A^{\to}) = 1 - \alpha$. Moreover, since $\hat{A} = A^{\uparrow} \cup B^{\uparrow}$ and $x(\hat{A}) = 1$, we also have $x(B^{\uparrow}) = 1 - \alpha$ and $x(B^{\to}) = \alpha$.

Therefore, using the fact that when $A^{\rightarrow} \cup B^{\rightarrow}$ is reduced, exactly one edge in $A^{\uparrow} \cup B^{\uparrow}$ is selected (and also exactly one edge in $A^{\rightarrow} \cup B^{\rightarrow}$ is selected since it is a bottom edge bundle), and marginals are preserved given the reduction, we conclude that

$$\mathbb{P}\left[a_1' \text{ happy} | A^{\rightarrow} \cup B^{\rightarrow} \text{ reduced}\right] = \mathbb{P}\left[A_T = B_T = 1 | A^{\rightarrow} \cup B^{\rightarrow} \text{ reduced}\right] = \alpha^2 + (1 - \alpha)^2.$$

Now, we calculate $\mathbb{E}\left[s_{\mathbf{f}}\right]$. First, note that \mathbf{f} may have to increase to compensate either for reduced edges in $A^{\uparrow} \cup B \uparrow$ or in $A^{\rightarrow} \cup B^{\rightarrow}$. For the sake of this discussion, suppose that $A^{\uparrow} \cup B^{\uparrow}$ is a set of top edges. Then, in the worst case we need to increase \mathbf{f} by $p\tau$ in expectation to fix the cuts a_1, a_2 due to the reduction in $A^{\uparrow} \cup B^{\uparrow}$. Now, we calculate the expected increase due to the reduction in $A^{\rightarrow} \cup B^{\rightarrow}$. The crucial observation is that edges in $A^{\rightarrow} \cup B^{\rightarrow}$ are reduced simultaneously, so both cuts $\delta(a_1)$ and $\delta(a_2)$ can be fixed simultaneously by an increase in $s_{\mathbf{f}}$. Therefore, when they are both odd, it suffices for \mathbf{f} to increase by

$$\max\{x(A^{\rightarrow}), x(B^{\rightarrow})\}\beta = \max\{\alpha, 1 - \alpha\}\beta,$$

to fix cuts a_1 , a_2 . Putting this together, we get

$$\mathbb{E}\left[s_{\mathbf{f}}\right] = -p\beta + \mathbb{E}\left[\text{increase due to } A^{\rightarrow} \cup B^{\rightarrow}\right] + \mathbb{E}\left[\text{increase due to } A^{\uparrow} \cup B^{\uparrow}\right]$$

$$\leq -p\beta + p\beta \max_{\alpha \in [1/2,1]} \alpha[1 - \alpha^2 - (1 - \alpha)^2] + p\tau$$

which, since $\max_{\alpha \in [1/2,1]} \alpha [1 - \alpha^2 - (1 - \alpha)^2] = 8/27$ and $\tau = 0.571\beta$ is

$$= p\beta(-1 + \frac{8}{27} + 0.571) = -0.13p\beta.$$

Dealing with x_u **close to** 1. ⁸ Now, suppose that $\mathbf{e} = (u, v)$ is a top edge bundle with $x_u := x(\delta^{\uparrow}(u))$ is close to 1. Then, the analysis in Example 3.4, bounding $r := \mathbb{P}\left[\delta(u)_T \text{ odd} \middle| g \text{ reduced}\right]$ away from 1 for an edge $g \in \delta^{\uparrow}(u)$ doesn't hold. To address this, we consider two cases: The first case, is that the edges in $\delta^{\uparrow}(u)$ break up into many groups that end at different levels in the hierarchy. In this case, we can analyze r separately for the edges that end at any given level, taking advantage of the independence between the trees chosen at different levels of the hierarchy.

The second case is when nearly all of the edges in $\delta^{\uparrow}(u)$ end at the same level, for example, they are all in $\delta^{\rightarrow}(u')$ where p(u') is a degree cut. In this case, we introduce a more complex (2-1-1) reduction rule for these edges. The observation is that from the perspective of these edges u' is a "pseudo-triangle". That is, it looks like a triangle cut, with atoms u and $u' \setminus u$ where $\delta(u) \cap \delta(u')$ corresponds to the "A"-side of the triangle.

⁸Some portions of this discussion might be easier to understand after reading the rest of the paper.

Now, we define this more complex 2-1-1 reduction rule: Consider a top edge $\mathbf{f} = (u', v') \in \delta^{\rightarrow}(u')$. So far, we only considered the following reduction rule for \mathbf{f} : If both u', v' are degree cuts, \mathbf{f} reduces when they are both even in the tree; otherwise if say u' is a triangle cut, \mathbf{f} reduces when it is 2-1-1 good w.r.t., u' (and similarly for v'). But clearly these rules ignore the pseudo triangle. The simplest adjustment is, if u' is a pseudo triangle with partition $(u, u' \setminus u)$, to require \mathbf{f} to reduce when $A_T = B_T = 1$ and v' is happy. However, as stated, it is not clear that the sets A and B are well-defined. For example, u' could be an actual triangle or there could be multiple ways to see u' as a pseudo triangle only one of which is $(u, u' \setminus u)$. Our solution is to find the *smallest* disjoint pair of cuts $a, b \subset u'$ in the hierarchy such that $x(\delta(a) \cap \delta(u')), x(\delta(b) \cap \delta(u')) \geq 1 - \epsilon_{1/1}$, where $\epsilon_{1/1}$ is a fixed universal constant, and then let $A = \delta(a) \cap \delta(u'), B = \delta(b) \cap \delta(u')$ and $C = \delta(u') \setminus A \setminus B$ (see Fig. 6 for an example). Then, we say \mathbf{f} is 2-1-1 happy w.r.t., u' if $A_T = B_T = 1$ and $C_T = 0$.

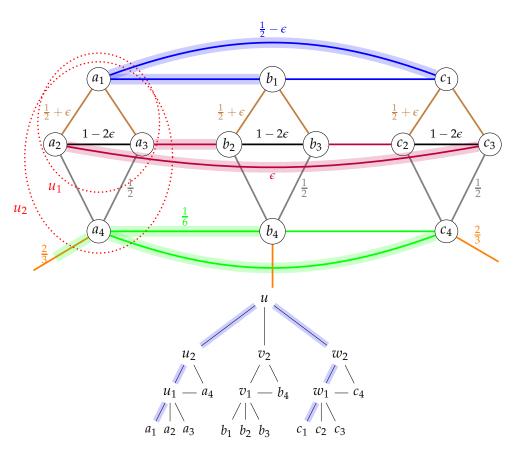

Figure 6: Part of the hierarchy of the graph is shown on top. Edges of the same color have the same fraction and $\epsilon \gg \eta$ is a small constant. u_1 corresponds to the degree cut $\{a_1,a_2,a_3\}$, u_2 corresponds to the triangle cut $\{u_1,a_4\}$ and u corresponds to the degree cut containing all of the vertices shown. Observe that edges in $\delta^{\uparrow}(a_1)$ are top edges in the degree cut u. If $\epsilon < \frac{1}{2}\epsilon_{1/1}$ then the (A,B,C)-degree partitioning of edges in $\delta(u_2)$ is as follows: $A = \delta(a_1) \cap \delta(u_2)$ are the blue highlighted edges each of fractional value $1/2 - \epsilon$, $1/2 - \epsilon$,

A few observations are in order:

- Since u is a candidate for, say a, it must be that a is a descendent of u in the hierarchy (or equal to u). In addition, b cannot simultaneously be in u, since $a \cap b = \emptyset$ and $x(\delta(u) \cap \delta(u')) \le 1$ by Lemma 2.7. So, when f is 2-1-1 happy w.r.t. u' we get $(\delta(u) \cap \delta(u'))_T = 1$.
- If u' = (X, Y) is a actual triangle cut, then we must have $a \subseteq X, b \subseteq Y$. So, when **f** is 2-1-1 happy w.r.t. u', we know that u' is a happy triangle, i.e., $(\delta(X) \cap \delta(u'))_T = 1$ and $(\delta(Y) \cap \delta(u'))_T = 1$.

Now, suppose for simplicity that all top edges in $\delta(u')$ are 2-1-1 good w.r.t. u'. Then, when an edge $g \in \delta(u) \cap \delta(u')$ is reduced, $(\delta(u) \cap \delta(u'))_T = 1$, so

$$\mathbb{P}\left[\delta(u)_T \text{ odd} | g \text{ reduced}\right] \leq \mathbb{P}\left[E(u, u' \setminus u)_T \text{ even} | g \text{ reduced}\right] \leq 0.57,$$

since edges in $E(u, u' \setminus u)$ are in the tree independent of the reduction and $\mathbb{E}\left[E(u, u' \setminus u)_T\right] \approx 1$.

Dealing with x_u **close to 0 and the matching.** We already discussed how the matching is modified to handle the existence of bad edges. We now observe that we can handle the case $x_u \approx 0$ by further modifying the matching. The key observation is that in this case, $x(\delta^{\rightarrow}(u)) \gg x(\delta^{\uparrow}(u))$. Roughly speaking, this enables us to find a matching in which each edge in $\delta^{\rightarrow}(u)$ has to increase about half as much as would normally be expected to fix the cut of u. This eliminates the need to prove a nontrivial bound on $\mathbb{P}\left[\delta(u)_T \text{ odd} | g \text{ reduced}\right]$. The details of the matching are in Section 6.

4 Polygons and the Hierarchy of Near Minimum Cuts

Let OPT be a minimum TSP solution, i.e., minimum cost Hamiltonian cycle and without loss of generality assume it visits u_0 and v_0 consecutively (recall that $c(u_0, v_0) = 0$). We write E^* to denote the edges of OPT and we write e^* to denote an edge of OPT. Analogously, we use $s^*: E^* \to \mathbb{R}_{>0}$ to denote the slack vector that we will construct for OPT edges.

Throughout this section we study η -near minimum cuts of G = (V, E, z) Note that these cuts are 2η -near minimum cuts w.r.t., x. For every such near minimum cut, (S, \overline{S}) , we identify the cut with the side, say S, such that $u_0, v_0 \notin S$. Equivalently, we can identify these cuts with an interval along the optimum cycle, OPT, that does not contain u_0, v_0 .

We will use "left" synonymously with "clockwise" and "right" synonymously with "counter-clockwise." We say a vertex is to the left of another vertex if it is to the left of that vertex and to the right of edge $e_0 = (u_0, v_0)$. Otherwise, we say it is to the right (including the root itself in this case).

Definition 4.1 (Crossed on the Left/Right, Crossed on Both Sides). For two crossing near minimum cuts S, S', we say S crosses S' on the left if the leftmost endpoint of S on the optimal cycle is to the left of the leftmost endpoint of S. Otherwise, we say S crosses S' on the right.

A near minimum cut is crossed on both sides if it is crossed on both the left and the right. We also say a a near minimum cut is crossed on one side if it is either crossed on the left or on the right, but not both.

4.1 Cuts Crossed on Both Sides

The following theorem is the main result of this section:

Theorem 4.2. Given OPT TSP tour with set of edges E^* , and a feasible LP solution x^0 of (1) with support $E_0 = E \cup \{e_0\}$ and let x be x^0 restricted to E. For any distribution μ of spanning trees with marginals x, if $\eta < 1/100$, then there is a random vector $s^* : E^* \to \mathbb{R}_{\geq 0}$ (the randomness in s^* depends exclusively on $T \sim \mu$) such that

- For any vector $s: E \to \mathbb{R}$ where $s_e \ge -x_e \eta/8$ for all e and for any η -near minimum cut S w.r.t., z = (x + OPT)/2 crossed on both sides where $\delta(S)_T$ is odd, we have $s(\delta(S)) + s^*(\delta(S)) \ge 0$;
- For any $e^* \in E^*$, $\mathbb{E}[s_{e^*}^*] \leq 5\eta^2$.

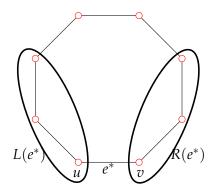

Figure 7: L and R for an OPT edge e^* .

For an OPT edge $e^* = (u, v)$, let $L(e^*)$ be the largest η -near minimum cut (w.r.t. z) containing u and not v which is crossed on both sides. Let $R(e^*)$ be the largest near minimum cut containing v and not u which is crossed on both sides. For example, see Fig. 7.

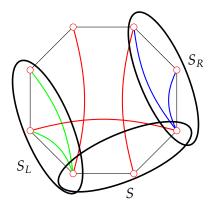

Figure 8: S is crossed on the left by S_L and on the right by S_R . In green are edges in $\delta(S)_L$, in blue edges in $\delta(S)_R$, and in red are edges in $\delta(S)_O$.

Definition 4.3. For a near minimum cut S that is crossed on both sides let S_L be the near minimum cut crossing S on the left which minimizes the intersection with S, and similarly for S_R ; if there are multiple sets crossing S on the left with the same minimum intersection, choose the smallest one to be S_L (and similar do for S_R).

We partition $\delta(S)$ into three sets $\delta(S)_L$, $\delta(S)_R$ and $\delta(S)_O$ as in Fig. 8 such that

$$\delta(S)_{L} = E(S \cap S_{L}, S_{L} \setminus S)$$

$$\delta(S)_{R} = E(S \cap S_{R}, S_{R} \setminus S)$$

$$\delta(S)_{O} = \delta(S) \setminus (\delta(S)_{L} \cup \delta(S)_{R})$$

For an OPT edge e^* define an (increase) event (of second type) $\mathcal{I}_2(e^*)$ as the event that at least one of the following *does not* hold.

$$|T \cap \delta(L(e^*))_R| = 1, |T \cap \delta(R(e^*))_L| = 1, T \cap \delta(L(e^*))_O = \emptyset, \text{ and } T \cap \delta(R(e^*))_O = \emptyset.$$
 (11)

In the proof of Theorem 4.2 we will increase an OPT edge e^* whenever $\mathcal{I}_2(e^*)$ occurs.

Lemma 4.4. For any OPT edge e^* , $\mathbb{P}\left[\mathcal{I}_2(e^*)\right] \leq 18\eta$.

Proof. Fix e^* . To simplify notation we abbreviate $L(e^*)$, $R(e^*)$ to L, R. Since L is crossed on both sides, L_L , L_R are well defined. Since by Lemma 2.5 $L_L \cap L$, $L_L \setminus L$ are 4η -near min cuts and L is 2η -near mincut with respect to x, by Corollary 2.24, $\mathbb{P}\left[|T \cap \delta(L)_L| = 1\right] \geq 1 - 5\eta$. Similarly, $\mathbb{P}\left[|T \cap \delta(R)_L| = 1\right] \geq 1 - 5\eta$. On the other hand, since L, L_L , L_R are 2η -near min cuts, by Lemma 2.6, $x(E(L \cap L_R, L_R))$, $x(E(L \cap L_L, L_L)) \geq 1 - \eta$. Therefore

$$x(\delta(L)_O) \leq 2 + 2\eta - x(E(L \cap L_R, L_R)) - x(E(L \cap L_L, L_L)) \leq 4\eta.$$

It follows that $\mathbb{P}\left[T \cap \delta(L)_O = \emptyset\right] \ge 1 - 4\eta$. Similarly, $\mathbb{P}\left[T \cap \delta(R)_O = \emptyset\right] \ge 1 - 4\eta$. Finally, by the union bound, all events occur simultaneously with probability at least $1 - 18\eta$. So, $\mathbb{P}\left[\mathcal{I}_2(e^*)\right] \le 18\eta$ as desired.

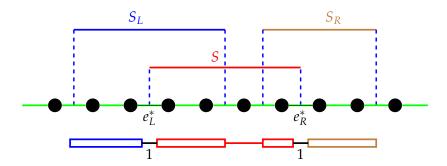

Figure 9: Setting of Lemma 4.5. Here we zoom in on a portion of the optimal cycle and assume the root is not shown. If $\mathcal{I}_2(e_L^*)$ does not occur then $E(S \cap S_L, S_L \setminus S)_T = 1$.

Lemma 4.5. Let S be a cut which is crossed on both sides and let e_L^* , e_R^* be the OPT edges on its interval where e_L^* is the edge further clockwise. Then, if $\delta(S)_T \neq 2$, at least one of $\mathcal{I}_2(e_L^*)$, $\mathcal{I}_2(e_R^*)$ occurs.

Proof. We prove by contradiction. Suppose none of $\mathcal{I}_2(e_L^*)$, $\mathcal{I}_2(e_R^*)$ occur; we will show that this implies $\delta(S)_T = 2$.

Let $R = R(e_L^*)$; note that S is a candidate for $R(e_L^*)$, so $S \subseteq R$. Therefore, $S_L = R_L$ and we have

$$\delta(R)_L = E(R \cap R_L, R_L \setminus R) = E(R \cap S_L, S_L \setminus R) = \delta(S)_L.$$

where we used $S \cap S_L = R \cap S_L$ and that $S_L \setminus S = S_L \setminus R$. Similarly let $L = L(e_R^*)$, and, we have $\delta(L)_R = \delta(S)_R$.

Now, since $\mathcal{I}_2(e_L^*)$ has not occurred, $1 = |T \cap \delta(R)_L| = |T \cap \delta(S)_L|$, and since $\mathcal{I}_2(e_R^*)$ has not occurred, $1 = |T \cap \delta(L)_R| = |T \cap \delta(S)_R|$, where $L = L(e_R^*)$. So, to get $\delta(S)_T = 2$, it remains to show that $T \cap \delta(S)_O = \emptyset$. Consider any edge $e = (u, v) \in \delta(S)_O$ where $u \in S$. We need to show $e \notin T$. Assume that v is to the left of S (the other case can be proven similarly). Then $e \in \delta(R)$. So, since e goes to the left of e, either $e \in E(R \cap R_L, R_L \setminus R)$ or $e \in \delta(R)_O$. But since $e \notin \delta(S)_L = \delta(R)_L$, we must have $e \in \delta(R)_O$. So, since $\mathcal{I}_2(e_L^*)$ has not occurred, $e \notin T$ as desired.

Proof of Theorem 4.2. For any OPT edge e^* whenever $\mathcal{I}_2(e^*)$ occurs, define $s_{e^*}^* = \eta/3.9$. Then, by Lemma 4.4, $\mathbb{E}\left[s_{e^*}\right] \leq 18\eta/3.9$ and for any 2η -near min cut S (w.r.t., x) that is crossed on both sides if $\delta(S)_T$ is odd, then at least one of $\mathcal{I}_2(e_L^*)$, $\mathcal{I}_w(e_R^*)$ occurs, so

$$s(\delta(S)) + s^*(\delta(S)) \ge -x(\delta(S))\eta/8 + s^*_{e^*_L} + s^*_{e^*_R} \ge -(2+2\eta)\eta/8 + \eta/3.9 \ge 0$$

for $\eta < 1/100$ as desired.

4.2 Proof of Main Technical Theorem

The following theorem is the main result of this section.

Theorem 4.6. Let x^0 be a feasible solution of LP (1) with support $E_0 = E \cup \{e_0\}$ and x be x^0 restricted to E. Let μ be the max entropy distribution with marginals x. For $\eta \leq 10^{-12}$, there is a set $E_g \subset E \setminus \delta(\{u_0, v_0\})$ of good edges and two functions $s: E_0 \to \mathbb{R}$ and $s^*: E^* \to \mathbb{R}_{>0}$ (as functions of $T \sim \mu$) such that

- (i) For each edge $e \in E_g$, $s_e \ge -x_e \eta/8$ and for any $e \in E \setminus E_g$, $s_e = 0$.
- (ii) For each η -near-min-cut S w.r.t. z, if $\delta(S)_T$ is odd, then $s(\delta(S)) + s^*(\delta(S)) \geq 0$.
- (iii) We have $\mathbb{E}[s_e] \leq -\epsilon_P \eta x_e$ for all edges $e \in E_g$ and $\mathbb{E}[s_{e^*}^*] \leq 45\eta^2$ for all OPT edges $e^* \in E^*$. for ϵ_P defined in (31).
- (iv) For every η -near minimum cut S of z crossed on (at most) one side such that $S \neq V \setminus \{u_0, v_0\}$, $x(\delta(S) \cap E_g) \geq 3/4$.

Before proving this theorem we use it to prove the main technical theorem from the previous section.

Theorem 3.1 (Main Technical Theorem). Let x^0 be a solution of LP (1) with support $E_0 = E \cup \{e_0\}$, and x be x^0 restricted to E. Let z := (x + OPT)/2, $\eta \le 10^{-12}$ and let μ be the max-entropy distribution with marginals x. Also, let E^* denote the support of OPT. There are two functions $s: E_0 \to \mathbb{R}$ and $s^*: E^* \to \mathbb{R}_{>0}$ (as functions of $T \sim \mu$), , such that

- i) For each edge $e \in E$, $s_e \ge -x_e \eta/8$.
- ii) For each η -near-min-cut S of z, if $\delta(S)_T$ is odd, then $s(\delta(S)) + s^*(\delta(S)) \geq 0$.
- iii) For every OPT edge e^* , $\mathbb{E}\left[s_{e^*}^*\right] \leq 45\eta^2$ and for every LP edge $e \neq e_0$, $\mathbb{E}\left[s_e\right] \leq -x_e \epsilon_P \eta/2$ for ϵ_P defined in (31).

Proof of Theorem 3.1. Let E_g be the good edges defined in Theorem 4.6 and let $E_b := E \setminus E_g$ be the set of bad edges. We define a new vector $\tilde{s} : E \cup \{e_0\} \to \mathbb{R}$ as follows:

$$\tilde{s}(e) \leftarrow \begin{cases} \infty & \text{if } e = e_0 \\ -x_e \eta / 8 & \text{if } e \in E_b, \\ x_e \eta / 4 & \text{otherwise.} \end{cases}$$
 (12)

Let \tilde{s}^* the vector in Theorem 4.2. We claim that for any η -near minimum cut S w.r.t., z such that $\delta(S)_T$ is odd, we have

$$\tilde{s}(\delta(S)) + \tilde{s}^*(\delta(S)) \ge 0.$$

To check this note by (iv) of Theorem 4.6 for every set $S \neq V \setminus \{u_0, v_0\}$ crossed on at most one side,

$$\tilde{s}(\delta(S)) + \tilde{s}^*(\delta(S)) \ge \tilde{s}(\delta(S)) \ge \frac{\eta}{4} \tilde{s}(E_g \cap \delta(S)) - \frac{\eta}{8} \tilde{s}(E_b \cap \delta(S)) \ge 0.$$
 (13)

For $S = V \setminus \{u_0, v_0\}$, we have $\delta(S)_T = \delta(u_0)_T + \delta(v_0)_T = 2$ with probability 1. Finally, for any odd cut S crossed on both sides, by Theorem 4.2 and the fact that $\tilde{s}_e \ge -\eta x_e/8$ for all e, the inequality holds.

Now, we are ready to define s, s^* . Let \hat{s}, \hat{s}^* be the s, s^* of Theorem 4.6 respectively. Define $s = \alpha \tilde{s} + (1 - \alpha)\hat{s}$ and similarly define $s^* = \alpha \tilde{s}^* + (1 - \alpha)\hat{s}^*$ for some α that we choose later. We prove all three conclusions for s, s^* . (i) follows by (i) of Theorem 4.6 and Eq. (12). (ii) follows by (ii) Theorem 4.6 and Eq. (13) above. It remains to verify (iii). For any OPT edge e^* , $\mathbb{E}\left[s_{e^*}^*\right] \leq 45\eta^2$ by (iii) of Theorem 4.6 and the construction of \tilde{s}^* . On the other hand, by (iii) of Theorem 4.6 and Eq. (12),

$$\mathbb{E}[s_e] \leq x_e(\alpha \eta/4 - (1-\alpha)\epsilon_P \eta), \forall e \in E_g,$$

$$\mathbb{E}[s_e] = -x_e(1-\alpha)\eta/8, \forall e \in E_b.$$

Setting $\alpha = \epsilon_P$ we get $\mathbb{E}\left[s_e\right] \le -\epsilon_P \eta x_e/2$ for $e \in E_g$ and $\mathbb{E}\left[s_e\right] \le -x_e \eta/9$ for $e \in E_b$ as desired. \square

4.3 Structure of Polygons of Cuts Crossed on One Side

Definition 4.7 (Connected Component of Crossing Cuts). Given a family of cuts crossed on at most one side, construct a graph where two cuts are connected by an edge if they cross. Partition this graph into maximal connected components. We call a path in this graph, a path of crossing cuts.

In the rest of this section we will focus on a single connected component C of cuts crossed on (at most) one side.

Definition 4.8 (Polygon). For a connected component C of crossing near min cuts that are crossed on one side, let a_0, \ldots, a_{m-1} be the coarsest partition of the vertices V, such that for all $0 \le i \le m-1$ and

for any $A \in \mathcal{C}$ either $a_i \subseteq A$ or $a_i \cap A = \emptyset$. These are called atoms. We assume a_0 is the atom that contains the special edge e_0 , and we call it the root. Note that for any $A \in \mathcal{C}$, $a_0 \cap A = \emptyset$.

Since every cut $A \in \mathcal{C}$ corresponds to an interval of vertices in V in the optimum Hamiltonian cycle, we can arrange a_0, \ldots, a_{m-1} around a cycle (in the counter clockwise order). We label the arcs in this cycle from 1 to m, where i+1 is the arc connecting a_i and a_{i+1} (and m is the name of the arc connecting a_{m-1} and a_0). Then every cut $A \in \mathcal{C}$ can be identified by the two arcs surrounding its atoms. Specifically, A is identified with arcs i, j (where i < j) if A contains atoms a_i, \ldots, a_{j-1} , and we write $\ell(A) = i, r(A) = j$. Note that A does not contain the root a_0 .

By construction for every arc $1 \le i \le m$, there exists a cut A such that $\ell(A) = i$ or r(A) = i. Furthermore, $A, B \in \mathcal{C}$ (with $\ell(A) \le \ell(B)$) cross iff $\ell(A) < \ell(B) < r(A) < r(B)$. See Fig. 10 for a visual example.

Notice that every atom of a polygon is an interval of the optimal cycle. In this section, we prove the following structural theorem about polygons of near minimum cuts crossed on one side.

Theorem 4.9 (Polygon Structure). For $\epsilon_{\eta} \geq 14\eta$ and any polygon with atoms $a_0...a_{m-1}$ (where a_0 is the root) the following holds:

- For all adjacent atoms a_i , a_{i+1} (also including a_0 , a_{m-1}), we have $x(E(a_i, a_{i+1})) \ge 1 \epsilon_n$.
- All atoms a_i (including the root) have $x(\delta(a_i)) \leq 2 + \epsilon_{\eta}$.
- $x(E(a_0, \{a_2, \ldots, a_{m-2}\})) \le \epsilon_{\eta}$.

The interpretation of this theorem is that the structure of a polygon converges to the structure of an actual integral cycle as $\eta \to 0$. The proof of the theorem follows from the lemmas in the rest of this subsection.

Definition 4.10 (Left and Right Hierarchies). For a polygon u corresponding to a connected component C of cuts crossed on one side, let L (the left hierarchy) be the set of all cuts $A \in C$ that are not crossed on the left. We call any cut in L open on the left. Similarly, we let R be the set of cuts that are open on the right. So, L, R is a partitioning of all cuts in C.

For two distinct cuts $A, B \in \mathcal{L}$ we say A is an ancestor of B in the left polygon hierarchy if $A \supseteq B$. We say A is a strict ancestor of B if, in addition, $\ell(A) \neq \ell(B)$. We define the right hierarchy similarly: A is a strict ancestor of B if $A \supseteq B$ and $r(A) \neq r(B)$.

We say B is a strict parent of A if among all strict ancestors of A in the (left or right) hierarchy, B is the one closest to A.

See Fig. 10 for examples of sets and their parent/ancestor relationships.

Fact 4.11. *If* A, B *are in the same hierarchy and they are not ancestors of each other, then* $A \cap B = \emptyset$.

Proof. If $A \cap B \neq \emptyset$ then they cross. So, they cannot be open on the same side.

This lemma immediately implies that the cuts in each of the left (and right) hierarchies form a laminar family.

Lemma 4.12. For $A, B \in \mathcal{R}$ where B is a strict parent of A, there exists a cut $C \in \mathcal{L}$ that crosses both A, B. Similarly, if $A, B \in \mathcal{L}$ and B is a strict parent of A, there exists a cut $C \in \mathcal{R}$ that crosses A, B.

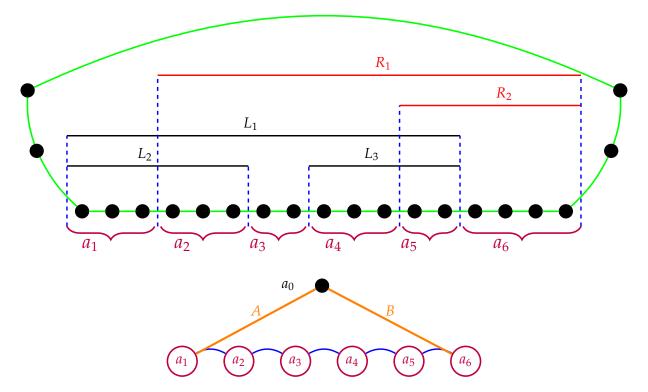

Figure 10: An example of a polygon with contracted atoms. In black are the cuts in the left polygon hierarchy, in red the cuts in the right polygon hierarchy. OPT edges around the cycle are shown in green. Here R_1 is an ancestor of R_2 , however it is not a strict ancestor of R_2 since they have the same right endpoint. L_1 is a strict ancestor and the strict parent of L_3 . By Theorem 4.9, every edge in the bottom picture represents a set of LP edges of total fraction at least $1 - \epsilon_{\eta}$.

Proof. Since we have a connected component of near min cuts, there exists a path of crossing cuts from A to B. Let $P = (A = C_0, C_1, \dots, C_k = B)$ be the shortest such path. We need to show that k = 2.

First, since C_1 crosses C_0 and C_0 is open on right, we have

$$\ell(C_1) < \ell(C_0) < r(C_1) < r(C_0).$$

Let I be the *closed* interval $[\ell(C_1), r(C_0)]$. Note that $C_k = B$ has an endpoint that does not belong to I. Let C_i be the *first* cut in the path with an endpoint not in I (definitely i > 1). This means $C_{i-1} \subseteq I$; so, since C_{i-1} crosses C_i , exactly one of the endpoints of C_i is strictly inside I. We consider two cases:

Case 1: $r(C_i) > r(C_0)$. In this case, C_i must be crossed on the left (by C_{i-1}) and $C_i \in \mathcal{R}$ and it does not cross C_0 . So, $C_0 \subseteq C_i$ and

$$\ell(C_1) < \ell(C_i) \le \ell(C_0)$$

where the first inequality uses that the left endpoint of C_i is strictly inside I. Therefore, C_1 crosses both of C_0 , C_i , and C_i is a strict ancestor of $A = C_0$. If $C_i = B$ we are done, otherwise, $A \subseteq B \subseteq C_i$, but since C_1 crosses both A and C_i , it also crosses B and we are done.

Case 2: $\ell(C_i) < \ell(C_1)$. In this case, C_i must be crossed on the right (by C_{i-1}) and $C_i \in \mathcal{L}$ and it does not cross C_1 . So, we must have

$$r(C_1) \leq r(C_i) < r(C_0),$$

where the second inequality uses that the right endpoint of C_i is strictly inside I. But, this implies that C_i also crosses C_0 . So, we can obtain a shorter path by excluding all cuts C_1, \ldots, C_{i-1} and that is a contradiction.

Lemma 4.13. Let $A, B \in \mathcal{R}$ such that $A \cap B = \emptyset$, i.e., they are not ancestors of each other. Then, they have a common ancestor, i.e., there exists a set $C \in \mathcal{R}$ such that $A, B \subseteq C$.

Proof. WLOG assume $r(A) \le \ell(B)$. Let C be the highest ancestor of A in the hierarchy, i.e., C has no ancestor. For the sake of contradiction suppose $B \cap C = \emptyset$ (otherwise, C is an ancestor of B and we are done). So, $r(C) \le \ell(B)$. Consider the path of crossing cuts from C to B, say $C = C_0, \ldots, C_k = B$.

Let C_i be the first cut in this path such that $r(C_i) > r(C_0)$. Note that such a cut always exists as r(B) > r(C). Since C_{i-1} crosses C_i and $r(C_{i-1}) \le r(C_0)$, C_{i-1} crosses C_i on the left and C_i is open on the right. We show that C_i is an ancestor of $C = C_0$ and we get a contradiction to C_0 having no ancestors (in \mathcal{R}). If $\ell(C_0) < \ell(C_i)$, then C_i crosses C_0 on the right and that is a contradiction. So, we must have $C_0 \subseteq C_i$, i.e., C_i is an ancestor of C_0 .

It follows from the above lemma that each of the left and right hierarchies have a unique cut with no ancestors.

Lemma 4.14. If A is a cut in \mathbb{R} such that r(A) < m, then A has a strict ancestor. And, similarly, if $A \in \mathcal{L}$ satisfies $\ell(A) > 1$, then it has a strict ancestor.

Proof. Fix a cut $A \in \mathcal{R}$. If there is a cut in $B \in \mathcal{R}$ such that r(B) > r(A), then either B is a strict ancestor of A in which case we are done, or $A \cap B = \emptyset$, but then by Lemma 4.13 A, B have a common ancestor C, and C must be a strict ancestor of A and we are done.

Now, suppose for any $R \in \mathcal{R}$, $r(R) \le r(A)$. So, there must be a cut $B \in \mathcal{L}$ such that r(B) > r(A) (otherwise we should have less than m atoms in our polygon). The cut B must be crossed on the right by a cut $C \in \mathcal{R}$. But then, we must have r(C) > r(B) > r(A) which is a contradiction.

Corollary 4.15. If $A \in \mathcal{C}$ has no strict ancestor, then r(A) = m if $A \in \mathcal{R}$ and $\ell(A) = 1$ otherwise.

Lemma 4.16 (Polygons are Near Minimum Cuts). $x(\delta(a_1 \cup \cdots \cup a_m)) \leq 2 + 4\eta$.

Proof. Let $A \in \mathcal{L}$ and $B \in \mathcal{R}$ be the unique cuts in the left/right hierarchy with no ancestors. Note that A and B are crossing (because there is a cut C that crosses A on the right, and B is an ancestor of C). Therefore, since A, B are both $2 + 2\eta$ near min cuts, by Lemma 2.5, $A \cup B$ is a $2 + 4\eta$ near min cut.

Lemma 4.17 (Root Neighbors). $x(E(a_0, a_1)), x(E(a_0, a_{m-1})) \ge 1 - 2\eta$.

Proof. Here we prove $x(E(a_0, a_1)) \ge 1 - 2\eta$. One can prove $x(E(a_0, a_{m-1})) \ge 1 - 2\eta$ similarly. Let $A \in \mathcal{L}$ and $B \in \mathcal{R}$ be the unique cuts in the left/right hierarchy with no ancestors. First, observe that if $\ell(B) = 2$, then since A, B are crossing, by Lemma 2.6 we have

$$x(E(A \setminus B, \overline{A \cup B})) = x(E(a_1, a_0)) \ge 1 - \eta.$$

as desired.

By definition of atoms, there exists a cut $C \in C$ such that either $\ell(C) = 2$ or r(C) = 2; but if r(C) = 2 we must have $\ell(C) = 1$ in which case C cannot be crossed, so this does not happen. So, we must have $\ell(C) = 2$. If $C \in \mathcal{R}$, then since C is a descendent of B, we must have $\ell(B) = 2$, and we are done by the previous paragraph.

Otherwise, suppose $C \in \mathcal{L}$. We claim that B crosses C. This is because, C is crossed on the right by some cut B' and B is an ancestor of B', so $B \cap C \neq \emptyset$ and $C \not\subseteq B$ since $\ell(B) > 2$. Therefore, by Lemma 2.5 $B \cup C$ is a $2 + 4\eta$ near min cut. Since A crosses $B \cup C$, by Lemma 2.6 we have

$$x(E(A \setminus (B \cup C), \overline{A \cup B \cup C})) = x(E(a_1, a_0)) \ge 1 - 2\eta$$

as desired. \Box

Lemma 4.18. For any pair of atoms a_i , a_{i+1} where $1 \le i \le m-2$ we have $x(\delta(\{a_i, a_{i+1}\})) \le 2+12\eta$, so $x(E(a_i, a_{i+1})) \ge 1-6\eta$.

Proof. We prove the following claim: There exists $j \le i$ such that $x(\delta(\{a_j, \ldots, a_{i+1}\})) \le 2 + 6\eta$. Then, by a similar argument we can find $j' \ge i + 1$ such that $x(\delta(\{a_i, \ldots, a_{j'}\})) \le 2 + 6\eta$. By Lemma 2.5 it follows that $x(\delta(\{a_i, a_{i+1}\})) \le 2 + 12\eta$. Since $x(\delta(a_i)), x(\delta(a_{i+1})) \ge 2$, we have

$$x(\delta(\{a_i, a_{i+1}\})) + 2x(E(a_i, a_{i+1})) \ge 4.$$

But due to the bound on $x(\delta(\{a_i, a_{i+1}\}))$ we must have $x(E(a_i, a_{i+1})) \ge 1 - 6\eta$ as desired.

It remains to prove the claim. First, observe that there is a cut A separating a_{i+1}, a_{i+2} (Note that if i+1=m-1 then $a_{i+2}=a_0$); so, either $\ell(A)=i+2$ or r(A)=i+2. If r(A)=i+2 then, A is the cut we are looking for and we are done. So, assume $\ell(A)=i+2$.

Case 1: $A \in \mathcal{L}$. Let $L \in \mathcal{L}$ be the strict parent of A. If $\ell(L) \leq i$ then we are done (since there is a cut $R \in \mathcal{R}$ crossing A, L on the right so $L \setminus (A \cup R)$ is the cut that we want. If $\ell(L) = i + 1$, then let L' be the strict parent of L). Then, there is a cut $R \in \mathcal{R}$ crossing A, L and a cut R' crossing L, L'. First, since both R, R' cross L (on the right) they have a non-empty intersection, so one of them say R' is an ancestor of the other (R) and therefore R' must intersect A. On the other hand, since R' crosses L and $\ell(L) = i + 1$, $\ell(R') \geq i + 2 = \ell(A)$. Since R' intersect A, either they cross, or $A \subseteq R'$, so we must have $x(\delta(A \cup R)) \leq 2 + 4\eta$. Finally, since R' crosses L' (on the right) we have $x(\delta(L' \setminus (A \cup R))) \leq 2 + 6\eta$ and $L' \setminus (A \cup R)$ is our desired set.

Case 2: $A \in \mathcal{R}$. We know that A is crossed on the left by, say, $L \in \mathcal{L}$. If $\ell(L) \leq i$, we are done, since then $L \setminus A$ is the cut that we seek and we get $x(\delta(L \setminus A)) \leq 2 + 4\eta$.

Suppose then that $\ell(L) = i + 1$. Let L' be the strict parent of L, which must have $\ell(L') \le i$. If L' crosses A, then $L' \setminus A$ is the cut we seek and we get $x(\delta(L \setminus A)) \le 2 + 4\eta$.

Finally, if L' doesn't cross A, i.e., $r(A) \le r(L')$, then consider the cut $R \in \mathcal{R}$ that crosses L and L' on the right. Since r(L) < r(A), and A is not crossed on the right, it must be that $\ell(R) = i + 2$. In this case, $L' \setminus R$ is the cut we want, and we get $x(\delta(L' \setminus R)) \le 2 + 4\eta$.

Lemma 4.19 (Atoms are Near Minimum Cuts). *For any* $1 \le i \le m-1$, *we have* $x(\delta(a_i)) \le 2+14\eta$.

Proof. By Lemma 4.18, $x(E(\{a_i, a_{i+1}\})) \le 2 + 12\eta$ (note that in the special case i = m-1 we take the pair a_{i-1}, a_i). There must be a 2η -near minimum cut C (w.r.t., x) separating a_i from a_{i+1} . Then either $a_i = C \cap \{a_i, a_{i+1}\}$ or $a_i = \{a_i, a_{i+1}\} \setminus C$. In either case, we get $x(\delta(a_i)) \le 2 + 14\eta$ by Lemma 2.5.

4.4 Happy Polygons

Definition 4.20 (A, B, C-Polygon Partition). Let u be a polygon with atoms a_0, \ldots, a_{m-1} with root a_0 where a_1, a_{m-1} are the atoms left and right of the root. The A, B, C-polygon partition of u is a partition of edges of $\delta(u)$ into sets $A = E(a_1, a_0)$ and $B = E(a_{m-1}, a_0)$, $C = \delta(u) \setminus A \setminus B$.

Note that by Theorem 4.9, x(A), $x(B) \ge 1 - \epsilon_{\eta}$ and $x(C) \le \epsilon_{\eta}$ where $\epsilon_{\eta} = 14\eta$ is defined in Theorem 4.9.

Definition 4.21 (Leftmost and Rightmost cuts). Let u be a polygon with atoms a_0, \ldots, a_m and arcs labelled $1, \ldots, m$ corresponding to a connected component C of η -near minimum cuts (w.r.t., z). We call any cut $C \in C$ with $\ell(C) = 1$ a leftmost cut of u and any cut $C \in C$ with $\ell(C) = m$ a rightmost cut of u. We also call u the leftmost atom of u (resp. u) the rightmost atom).

Observe that by Corollary 4.15, any cut that is not a leftmost or a rightmost cut has a strict ancestor.

Definition 4.22 (Happy Polygon). Let u be a polygon with polygon partition A, B, C. For a spanning tree T, we say that u is happy if

$$A_T$$
 and B_T odd, $C_T = 0$.

We say that u is left-happy (respectively right-happy) if

$$A_T$$
 odd, $C_T = 0$,

(respectively B_T odd, $C_T = 0$).

Definition 4.23 (Relevant Cuts). Given a polygon u corresponding to a connected component C of cuts crossed on one side with atoms a_0, \ldots, a_{m-1} , define a family of relevant cuts

$$C' = C \cup \{a_i : 1 \le i \le m - 1, z(\delta(a_i)) \le 2 + \eta\}.$$

Note that atoms of u are always $\epsilon_{\eta}/2$ -near minimum cuts w.r.t., z but not necessarily η -near minimum cuts. The following theorem is the main result of this section.

Theorem 4.24 (Happy Polygons and Cuts Crossed on One Side). Let G = (V, E, x) for x be an LP solution and z = (x + OPT)/2. For a connected component C of near minimum cuts of z, let u be the polygon with atoms $a_0, a_1...a_{m-1}$ with polygon partition A, B, C. For μ an arbitrary distribution of spanning trees with marginals x, there is a random vector $s^* : E^* \to \mathbb{R}_{\geq 0}$ (as a function of $T \sim \mu$) such that for any vector $s : E \to \mathbb{R}$ where $s_e \geq -\eta x_e/8$ for all $e \in E$ the following holds:

• If u is happy then, for any cut $S \in \mathcal{C}'$ if $\delta(S)_T$ is odd then we have $s(\delta(S)) + s^*(\delta(S)) \geq 0$,

- If u is left happy, then for any $S \in \mathcal{C}'$ that is not a rightmost cut or the rightmost atom, if $\delta(S)_T$ is odd, then we have $s(\delta(S)) + s^*(\delta(S)) \ge 0$. Similarly, if u is right happy then for any cut $S \in \mathcal{C}'$ that is not a rightmost cut or the rightmost atom, the latter inequality holds.
- $\mathbb{E}[s_{e^*}^*] \leq 40\eta^2$.

Before proving the above theorem, we study a special case.

Lemma 4.25 (Triangles as Degenerate Polygons). Let $S = X \cup Y$ where X, Y, S are ϵ_{η} -near min cuts (w.r.t., x) and each of these sets is a contiguous interval around the OPT cycle. Then, viewing X as a_1 and Y as a_2 (and $a_0 = \overline{X \cup Y}$) the above theorem holds viewing S as a degenerate polygon.

Proof. In this case $A = E(a_1, a_0)$, $B = E(a_2, a_0)$, $C = \emptyset$. For the OPT edge e^* between X, Y we define $\mathcal{I}_1(e^*)$ to be the event that at least one of $T \cap E(X)$, $T \cap E(Y)$, $T \cap E(S)$ is not a tree. Whenever this happens we define $s_{e^*}^* = \eta/3.9$. If S is left-happy we need to show when $\delta(X)_T$ is odd, then $s(\delta(X)) + s^*(\delta(X)) \ge 0$. This is because when S is left-happy we have $A_T = 1$ (and $C_T = 0$), so either $\mathcal{I}_1(e^*)$ does not happen and we get $\delta(X)_T = 2$ or it happens in which case $s(\delta(X)) + s^*(\delta(X)) \ge 0$ as $s(\delta(X)) \ge -(2 + 2\eta)\eta/8$ and $s_{e^*}^* = \eta/3.9$. Finally, observe that by Corollary 2.24, $\mathbb{P}[\mathcal{I}_1(e^*)] \le 3\epsilon_\eta$, so $\mathbb{E}[s_{e^*}^*] = 3\epsilon_\eta \eta/3.9 \le 40\eta^2$.

Lemma 4.26. For every cut $A \in \mathcal{C}$ that is not a leftmost or a rightmost cut, $\mathbb{P}\left[\delta(A)_T = 2\right] \geq 1 - 22\eta$.

Proof. Assume $A \in \mathcal{R}$; the other case can be proven similarly. Let B be the strict parent of A. By Lemma 4.12 there is a cut $C \in \mathcal{L}$ which crosses A, B on their left. It follows by Lemma 2.5 that $C \setminus A$, $C \cap A$ are 4η near minimum cuts (w.r.t., x). So, by Corollary 2.24, $\mathbb{P}\left[E(A \cap C, C \setminus A)_T = 1\right] \geq 1 - 5\eta$. On the other hand, $B \setminus (A \cup C)$ is a 6η near minimum cut and $A \setminus C$, $B \setminus C$ are 4η near min cuts (w.r.t., x). So, by Corollary 2.24 $\mathbb{P}\left[E(A \setminus C, B \setminus (A \cup C))_T = 1\right] \geq 1 - 7\eta$.

Finally, by Lemma 2.6, $x(E(A \cap C, C \setminus A)), x(A \setminus C, B \setminus (A \cup C)) \ge 1 - 3\eta$. Since A is a 2η near min cut (w.r.t., x), all remaining edges have fractional value at most 8η , so with probability $1 - 8\eta$, T does not choose any of them. Taking a union bound over all of these events, $\mathbb{P}\left[\delta(A)_T = 2\right] \ge 1 - 22\eta$.

Lemma 4.27. For any atom $a_i \in \mathcal{C}'$ that is not the leftmost or the rightmost atom we have

$$\mathbb{P}[\delta(a_i)_T = 2] \ge 1 - 42\eta.$$

Proof. By Lemma 4.18, $x(\delta(\{a_i, a_{i+1}\})) \le 2 + 12\eta$, and by Lemma 4.19, $x(\delta(a_{i+1})) \le 2 + 14\eta$ (also recall by the assumption of lemma $x(\delta(a_i)) \le 2 + 2\eta$, Therefore, by Corollary 2.24,

$$\mathbb{P}\left[E(a_i, a_{i+1})_T = 1\right], \mathbb{P}\left[E(a_{i-1}, a_i)_T = 1\right] \geq 1 - 14\eta,$$

where the second inequality holds similarly. Also, by Lemma 4.18, $x(E(a_{i-1}, a_i))$, $x(E(a_i, a_{i+1})) \ge 1 - 6\eta$. Since $x(\delta(a_i)) \le 2 + 2\eta$, $x(E(a_i, \overline{a_{i-1} \cup a_i \cup a_{i+1}})) \le 14\eta$. So,

$$\mathbb{P}\left[T \cap E(a_i, \overline{a_{i-1} \cup a_i \cup a_{i+1}}) = \emptyset\right] \ge 1 - 14\eta.$$

Finally, by the union bound all events occur with probability at least $1-42\eta$.

Let e_1^*, \ldots, e_m^* be the OPT edges mapped to the arcs $1, \ldots, m$ of the component \mathcal{C} respectively.

Lemma 4.28. There is a mapping of cuts in C' to OPT edges $e_2^*, \dots e_{m-1}^*$ such that each OPT edge has at most 4 cuts mapped to it.

Proof. Consider first the set of cuts in $\mathcal{C}'_R := \mathcal{R} \cup \{a_i : 1 \le i \le m-1, z(\delta(a_i)) \le 2 + \eta\}$. Observe that this is also a laminar family. We define a map from cuts in \mathcal{C}'_R to OPT edges such that every OPT edge e_2^*, \ldots, e_{m-1}^* gets at most 2 cuts mapped to it. A similar argument works for cuts in \mathcal{L} . For any $2 \le i \le m-1$, we map

$$\mathrm{argmax}_{A \in \mathcal{R}: \ell(A) = i} |A|$$
 and $\mathrm{argmax}_{A \in \mathcal{R}: r(A) = i} |A|$

to e_i^* . By construction, each OPT edge gets at most two cuts mapped to it. Furthermore, we claim every cut $A \in \mathcal{C}_R'$ gets mapped to at least one OPT edge. For the sake of contradiction let $A \in \mathcal{C}_R'$ be a cut that is not mapped to any OPT edge. Note that A is not a_1 or a_{m-1} and that if $A \in \mathcal{R}$, $\ell(A) \neq 1$. Furthermore, if $A \in \mathcal{R}$ and r(A) = m, then A is definitely the largest cut with left endpoint $\ell(A)$. So assume, $1 < \ell(A) = r(A) < m$. Let $B = \operatorname{argmax}_{B \in \mathcal{R}: \ell(B) = \ell(A)} |B|$ and let $C = \operatorname{argmax}_{B \in \mathcal{R}: r(C) = r(A)} |C|$. Since A is not mapped to any OPT edge, we must have $B, C \neq A$. But that implies $A \subsetneq B, C$. And this means B, C cross; but this is a contradiction with \mathcal{R} being a laminar family.

If *A* is mapped to two OPT edges in the above construction, we choose one of them arbitrarily.

Recall for a cut $L \in \mathcal{L}$, L_R is the near minimum cut crossing L on the right that minimizes the intersection (see Definition 4.3).

Definition 4.29 (Happy Cut). We say a leftmost cut $L \in \mathcal{L}$ is happy if

$$|T \cap E(L_R \cap L, L_R \setminus L)| = 1, \delta(L, \overline{a_0 \cup L \cup L_R}) = \emptyset.$$

Also, we say the leftmost atom a_1 *is* happy *if*

$$|T \cap E(a_1, a_2)| = 1, E(a_1, a_3 \cup \cdots \cup a_{m-1}) = \emptyset.$$

Similarly, define rightmost cuts in u or the rightmost atom in u to be happy.

Note that, by definition, if leftmost cut L is happy and u is left happy then L is even, i.e., $\delta(L)_T = 2$. Similarly, a_1 is even if it is happy and u is left-happy.

Lemma 4.30. For every leftmost or rightmost cut A in u that is η -near min cut w.r.t. z, $\mathbb{P}\left[A \text{ happy}\right] \geq 1 - 10\eta$, and for the leftmost atom a_1 (resp. rightmost atom a_{m-1}), if it is an η -near min cut then $\mathbb{P}\left[a_1 \text{ happy}\right] \geq 1 - 24\eta$ (resp. $\mathbb{P}\left[a_{m-1} \text{ happy}\right] \geq 1 - 24\eta$).

Proof. Recall that if A is a η -near min cut w.r.t. z then it is a 2η -near min cut w.r.t. x. We prove this for the leftmost cuts and the leftmost atom; the other case can be proven similarly. Consider a cut $L \in \mathcal{L}$. Since by Lemma 2.5 $L_R \cap L$, $L_R \setminus L$ are 4η near min cuts (w.r.t., x) and L_R is a 2η near min cut, by Corollary 2.24, $\mathbb{P}\left[E(L_R \cap L, L_R \setminus L)_T = 1\right] \geq 1 - 5\eta$. On the other hand, by Lemma 2.6, $x(E(L_R \cap L, L_R \setminus L)) \geq 1 - \eta$, and by Lemma 4.17, $x(E(L, a_0)) \geq 1 - 2\eta$. It follows that

$$x(L, \overline{a_0 \cup L \cup L_R}) \le 2 + 2\eta - (1 - \eta) - (1 - 2\eta) \le 5\eta.$$

Therefore, by the union bound, $\mathbb{P}[L \text{ happy}] \geq 1 - 10\eta$

Now consider the atom a_1 , and suppose it is an η near min cut. By Lemma 4.18, $x(\delta(\{a_1,a_2\})) \le 2 + 12\eta$ and by Lemma 4.19, $x(\delta(a_2)) \le 2 + 14\eta$. Therefore, by Corollary 2.24, $\mathbb{P}\left[E(a_1,a_2)_T = 1\right] \ge 1 - 14\eta$. On the other hand, by Lemma 4.18, $x(E(a_1,a_2)) \ge 1 - 6\eta$ and by Lemma 4.17, $x(E(a_1,a_0)) \ge 1 - 2\eta$. Therefore,

$$x(E(a_1, a_3 \cup \cdots \cup a_{m-1})) \le 2 + 2\eta - (1 - 6\eta) - (1 - 2\eta)) \le 10\eta.$$

Therefore, by the union bound, $\mathbb{P}[a_1 \text{ happy}] \geq 1 - 24\eta$ as desired.

Proof of Theorem 4.24. Consider an OPT edge e_i^* for 1 < i < m. We define an increase event $\mathcal{I}_1(e_i^*)$ of the first type as follows: This event occurs if at least one of the possible 4 cuts mapped to e_i^* in Lemma 4.28 is odd or if a leftmost cut $L \in \mathcal{L}$ assigned to u with r(L) = i is not happy or a rightmost cut $R \in \mathcal{R}$ assigned to u with l(R) = i is not happy (note in the special case that i = 2, L will be the leftmost atom if it is a near min cut, and similarly when i = m - 1, R will be the rightmost atom if it is a near min cut).

Whenever $\mathcal{I}_1(e_i^*)$ occurs, we define $s_{e_i^*}^* = \eta/3.9$, otherwise we let it be 0. First, observe that for any cut $S \in \mathcal{C}'$ that is not a leftmost or a rightmost cut/atom, if $\delta(S)_T$ is odd, then if e_i^* is the OPT edge that S is mapped to, it satisfies $s_{e_i^*}^* = \eta/3.9$, so

$$s(\delta(S)) + s^*(\delta(S)) \ge -x(\delta(S))\eta/8 + s^*(e_i^*) \ge -(2+2\eta)\eta/8 + \eta/3.9 \ge 0,$$

for $\eta < 1/100$. Now, suppose $S \in \mathcal{L}$ is the leftmost cut assigned to u and $\delta(S)_T$ is odd, and r(S) = i. If u is not left-happy there is nothing to prove. If u is left-happy, then we must have S is not happy, so $\mathcal{I}_1(e_i^*)$ occurs, so similar to the above inequality $s(\delta(S)) + s^*(\delta(S)) \geq 0$. The same holds for rightmost cuts and the leftmost/rightmost atoms if assigned to u.

It remains to upper bound $\mathbb{E}\left[e_i^*\right]$ for 1 < i < m. By Lemma 4.28 at most 4 cuts that are not leftmost or rightmost are mapped to e_i^* and at most two are atoms. By Lemma 4.26 and Lemma 4.27 and a union bound, all of these 4 cuts are even with probability at least $1-122\eta$. Also, by Lemma 4.30, at most one leftmost cut and rightmost cut are mapped to e_i^* , and $s_{e_i^*}^*$ is set to $\eta/3.9$ if either is not happy. Both of these cut will be happy with probability at least $1-20\eta$. In the special case that i=2 or i=m-2 one of these cuts could be the leftmost or rightmost atoms, in which case the probability that both leftmost and rightmost cuts are happy would be $1-34\eta$. Putting everything together, $\mathbb{P}\left[I_1(e_i^*)\right] \leq 156\eta$. So, $\mathbb{E}\left[s^*(e_i^*)\right] \leq 156\eta/3.9\eta = 40\eta$ as desired.

4.5 Hierarchy of Cuts and Proof of Theorem 4.6

Definition 4.31 (Hierarchy). For an LP solution x^0 with support $E_0 = E \cup \{e_0\}$ and x be x^0 restricted to E, a hierarchy \mathcal{H} is a laminar family of ϵ_{η} -near min cuts of G = (V, E, x) with root $V \setminus \{u_0, v_0\}$, where every cut $S \in \mathcal{H}$ is either a polygon cut (including triangles) or a degree cut and $u_0, v_0 \notin S$. For any (non-root) cut $S \in \mathcal{H}$, define the parent of S, p(S), to be the smallest cut $S' \in \mathcal{H}$ such that $S \subseteq S'$.

For a cut $S \in \mathcal{H}$, let $\mathcal{A}(S) := \{u \in \mathcal{H} : p(u) = S\}$. If S is a polygon cut, then we can order cuts in $\mathcal{A}(S)$, u_1, \ldots, u_{m-1} such that

•
$$A = E(\overline{S}, u_1), B = E(u_{m-1}, \overline{S})$$
 satisfy $x(A), x(B) \ge 1 - \epsilon_{\eta}$.

• For any
$$1 \le i < m-1$$
, $x(E(u_i, u_{i+1}) \ge 1 - \epsilon_{\eta}$.

• $C = \bigcup_{i=2}^{m-2} E(u_i, \overline{S})$ satisfies $x(C) \le \epsilon_{\eta}$.

We call the sets A, B, C the polygon partition of edges in $\delta(S)$. We say S is left-happy when A_T is odd and $C_T = 0$ and right happy when B_T is odd and $C_T = 0$ and happy when A_T , B_T are odd and $C_T = 0$.

We abuse notation, and for an (LP) edge e = (u, v) that is not a neighbor of u_0, v_0 , let p(e) denote the smallest⁹ cut $S' \in \mathcal{H}$ such that $u, v \in S'$. We say edge e is a **bottom edge** if p(e) is a polygon cut and we say it is a **top edge** if p(e) is a degree cut.

Note that when S is a polygon cut u_1, \ldots, u_{m-1} will be the atoms a_1, \ldots, a_{m-1} that we defined in the previous section, but a reader should understand this definition independent of the polygon definition that we discussed before; in particular, the reader no longer needs to worry about the details of specific cuts C that make up a polygon. Also, note that since $V \setminus \{u_0, v_0\}$ is the root of the hierarchy, for any edge $e \in E$ that is not incident to u_0 or v_0 , p(e) is well-defined; so all those edges are either bottom or top, and edges which are incident to u_0 or v_0 are neither bottom edges nor top edges.

The following observation is immediate from the above definition.

Observation 4.32. For any polygon cut $S \in \mathcal{H}$, and any cut $S' \in \mathcal{H}$ which is a descendant of S let $D = \delta(S') \cap \delta(S)$. If $D \neq \emptyset$, then exactly one of the following is true: $D \subseteq A$ or $D \subseteq B$ or $D \subseteq C$.

Theorem 4.33 (Main Payment Theorem). For an LP solution x^0 and x be x^0 restricted to E and a hierarchy \mathcal{H} for some $\epsilon_{\eta} \leq 10^{-10}$, the maximum entropy distribution μ with marginals x satisfies the following:

- i) There is a set of good edges $E_g \subseteq E \setminus \delta(\{u_0, v_0\})$ such that any bottom edge e is in E_g and for any (non-root) $S \in \mathcal{H}$ such that p(S) is a degree cut, we have $x(E_g \cap \delta(S)) \ge 3/4$.
- ii) There is a random vector $s: E_g \to \mathbb{R}$ (as a function of $T \sim \mu$) such that for all $e, s_e \geq -x_e \eta/8$ (with probability 1), and
- iii) If a polygon cut u with polygon partition A, B, C is not left happy, then for any set $F \subseteq E$ with p(e) = u for all $e \in F$ and $x(F) \ge 1 \epsilon_{\eta}/2$, we have

$$s(A) + s(F) + s^{-}(C) \ge 0$$
,

where $s^-(C) = \sum_{e \in C} \min\{s_e, 0\}$. A similar inequality holds if u is not right happy.

- iv) For every cut $S \in \mathcal{H}$ such that p(S) is not a polygon cut, if $\delta(S)_T$ is odd, then $s(\delta(S)) \geq 0$.
- v) For a good edge $e \in E_g$, $\mathbb{E}[s_e] \le -\epsilon_P \eta x_e$ (see Eq. (31) for definition of ϵ_P).

The above theorem is the main part of the paper in which we use that μ is a SR distribution. See Section 7 for the proof. We use this theorem to construct a random vector s such that essentially for all cuts $S \in \mathcal{H}$ in the hierarchy z/2 + s is feasible; furthermore for a large fraction of "good" edges we have that $\mathbb{E}[s_e]$ is negative and bounded away from 0.

As we will see in the following subsection, using part (iii) of the theorem we will be able to show that every leftmost and rightmost cut of any polygon is satisfied.

⁹in the sense of the number of vertices that it contains

In the rest of this section we use the above theorem to prove Theorem 4.6. We start by explaining how to construct \mathcal{H} . Given the vector z = (x + OPT)/2 run the following procedure on the OPT cycle with the family of η -near minimum cuts of z that are crossed on at most one side:

For every connected component \mathcal{C} of η near minimum cuts (w.r.t., z) crossed on at most one side, if $|\mathcal{C}| = 1$ then add the unique cut in \mathcal{C} to the hierarchy. Otherwise, \mathcal{C} corresponds to a polygon u with atoms a_0, \ldots, a_{m-1} (for some m > 3). Add $a_1, \ldots, a_{m-1}^{10}$ and $\bigcup_{i=1}^{m-1} a_i$ to \mathcal{H} . Note that since $z(\{u_0, v_0\}) = 2$, the root of the hierarchy is always $V \setminus \{u_0, v_0\}$.

Now, we name every cut in the hierarchy. For a cut S if there is a connected component of at least two cuts with union equal to S, then call S a polygon cut with the A, B, C partitioning as defined in Definition 5.18. If S is a cut with exactly two children X, Y in the hierarchy, then also call S a polygon cut¹¹, $A = E(X, \overline{X} \setminus Y)$, $B = E(Y, \overline{Y} \setminus X)$ and $C = \emptyset$. Otherwise, call S a degree cut.

Fact 4.34. *The above procedure produces a valid hierarchy.*

Proof. First observe that whenever $|\mathcal{C}| = 1$ the unique cut in \mathcal{C} is a 2η near min cut (w.r.t, x) which is not crossed. For a polygon cut S in the hierarchy, by Lemma 4.16, the set S is a ϵ_{η} near min cut w.r.t., x. If S is an atom of a polygon, then by Lemma 4.19 S is a ϵ_{η} near min cut.

Now, it remains to show that for a polygon cut S we have a valid ordering u_1,\ldots,u_k of cuts in $\mathcal{A}(S)$. If S is a non-triangle polygon cut, the u_1,\ldots,u_k are exactly atoms of the polygon of S and $x(A),x(B)\geq 1-\epsilon_\eta$ and $x(C)\leq \epsilon_\eta$ and $x(E(u_i,u_{i+1}))\geq 1-\epsilon_\eta$ follow by Theorem 4.9. For a triangle cut $S=X\cup Y$ because S,X,Y are ϵ_η -near min cuts (by the previous paragraph), we get $x(A),x(B)\geq 1-\epsilon_\eta$ as desired, by Lemma 2.7. Finally, since $x(\delta(X)),x(\delta(Y))\geq 2$ we have $x(E(X,Y))\geq 1-\epsilon_\eta$.

The following observation is immediate:

Observation 4.35. Each cut $S \in \mathcal{H}$ corresponds to a contiguous interval around OPT cycle. For a polygon u (or a triangle) with atoms a_0, \ldots, a_{m-1} for $m \geq 3$ we say an OPT edge e^* is interior to u if $e^* \in E^*(a_i, a_{i+1})$ for some $1 \leq i \leq m-2$. Any OPT edge e^* is interior to at most one polygon.

Theorem 4.6. Let x^0 be a feasible solution of LP (1) with support $E_0 = E \cup \{e_0\}$ and x be x^0 restricted to E. Let μ be the max entropy distribution with marginals x. For $\eta \leq 10^{-12}$, there is a set $E_g \subset E \setminus \delta(\{u_0, v_0\})$ of good edges and two functions $s: E_0 \to \mathbb{R}$ and $s^*: E^* \to \mathbb{R}_{\geq 0}$ (as functions of $T \sim \mu$) such that

- (i) For each edge $e \in E_g$, $s_e \ge -x_e \eta/8$ and for any $e \in E \setminus E_g$, $s_e = 0$.
- (ii) For each η -near-min-cut S w.r.t. z, if $\delta(S)_T$ is odd, then $s(\delta(S)) + s^*(\delta(S)) \geq 0$.
- (iii) We have $\mathbb{E}[s_e] \leq -\epsilon_P \eta x_e$ for all edges $e \in E_g$ and $\mathbb{E}[s_{e^*}^*] \leq 45\eta^2$ for all OPT edges $e^* \in E^*$. for ϵ_P defined in (31).
- (iv) For every η -near minimum cut S of z crossed on (at most) one side such that $S \neq V \setminus \{u_0, v_0\}$, $x(\delta(S) \cap E_g) \geq 3/4$.

¹⁰Notice that an atom may already correspond to a connected component, in such a case we do not add it in this step.

¹¹Think about such set as a *degenerate* polygon with atoms $a_1 := X$, $a_2 := Y$, $a_0 := \overline{X \cup Y}$. So, for the rest of this section we call them triangles and in later section we just think of them as polygon cuts.

Proof. Let E_g , s be as defined in Theorem 4.33, and let $s_{e_0} = \infty$. Also, let s^* be the sum of the s^* vectors from Theorem 4.2 and Theorem 4.24. (i) follows (ii) of Theorem 4.33. $\mathbb{E}\left[s_{e^*}^*\right] \leq 45\eta^2$ follows from Theorem 4.2 and Theorem 4.24 and the fact that every OPT edge is interior to at most one polygon. Also, $\mathbb{E}\left[s_e\right] \leq -\epsilon_P x_e$ for edges $e \in E_g$ follows from (v) of Theorem 4.33.

Now, we verify (iv): For any (non-root) cut $S \in \mathcal{H}$ such that p(S) is not a polygon cut $x(\delta(S) \cap E_g) \geq 3/4$ by (i) of Theorem 4.33. The only remaining η -near minimum cuts are sets S which are either atoms or near minimum cuts in the component \mathcal{C} corresponding to a polygon u. So, by Lemma 2.7, $x(\delta(S) \cap \delta(u)) \leq 1 + \epsilon_{\eta}$. By (i) of Theorem 4.33 all edges in $\delta(S) \setminus \delta(u)$ are in E_g . Therefore, $x(\delta(S) \cap E_g) \geq 1 - \epsilon_{\eta} \geq 3/4$.

It remains to verify (ii): We consider 4 groups of cuts:

Type 1: Near minimum cuts S such that $e_0 \in \delta(S)$. Then, since $s_{e_0} = \infty$, $s(\delta(S)) + s^*(\delta(S)) \ge 0$.

Type 2: Near minimum cuts $S \in \mathcal{H}$ where p(S) is not a polygon cut. By (iv) of Theorem 4.33 and that $s^* \geq 0$ the inequality follows.

Type 3: Near minimum cuts *S* crossed on both sides. Then, the inequality follows by Theorem 4.2 and the fact that $s_e \ge -\eta/8$ for all $e \in E$.

Type 4: Near minimum cuts S that are crossed on one side (and not in \mathcal{H}) or $S \in \mathcal{H}$ and p(S) is a (non-triangle) polygon cut. In this case S must be an atom or a η -near minimum cut (w.r.t., z) in some polygon $u \in \mathcal{H}$. If S is not a leftmost cut/atom or a rightmost cut/atom, then the inequality follows by Theorem 4.24. Otherwise, say S is a leftmost cut. If u is left-happy then by Theorem 4.24 the inequality is satisfied. Otherwise, for $F = \delta(S) \setminus \delta(u)$, by Lemma 2.7, we have $x(F) \geq 1 - \epsilon_{\eta}/2$. Therefore, by (iii) of Theorem 4.33 we have

$$s(\delta(S)) + s^*(\delta(S)) \ge s(A) + s(F) + s^-(C) \ge 0$$

as desired. Note that since S is a leftmost cut, we always have $A \subseteq \delta(S)$. But C may have an unpredictable intersection with $\delta(S)$; in particular, in the worst case only edges of C with negative slack belong to $\delta(S)$. A similar argument holds when S is the leftmost atom or a rightmost cut/atom.

Type 5: Near min cut S is the leftmost atom or the rightmost atom of a triangle u. This is similar to the previous case except we use Lemma 4.25 to argue that the inequality is satisfied when u is left happy.

4.6 Hierarchy Notation

In the rest of the paper we will not work with z, OPT edges, or the notion of polygons. So, practically, by Definition 4.31, from now on, a reader can just think of every polygon as a triangle. In the rest of the paper we adopt the following notation.

We abuse notation and call any $u \in A(S)$ an atom of S.

Definition 4.36 (Edge Bundles, Top Edges, and Bottom Edges). For every degree cut S and every pair of atoms $u, v \in A(S)$, we define a **top edge bundle** $\mathbf{f} = (u, v)$ such that

$$\mathbf{f} = \{e = (u', v') \in E : p(e) = S, u' \in u, v' \in v\}.$$

Note that in the above definition, u', v' are actual vertices of G.

For every polygon cut S, we define the **bottom edge bundle** $\mathbf{f} = \{e : p(e) = S\}$.

We will always use bold letters to distinguish top edge bundles from actual LP edges. Also, we abuse notation and write $x_e := \sum_{f \in e} x_f$ to denote the total fractional value of all edges in this bundle.

In the rest of the paper, unless otherwise specified, we work with edge bundles and sometimes we just call them edges.

For any $u \in \mathcal{H}$ with p(u) = S we write

$$\delta^{\uparrow}(u) := \delta(u) \cap \delta(S),$$

$$\delta^{\rightarrow}(u) := \delta(u) \setminus \delta(S).$$

$$E^{\rightarrow}(S) := \{e = (u_i, u_j) : u_i, u_j \in \mathcal{A}(S), u_i \neq u_j\}.$$

Also, for a set of edges $A \subseteq \delta(u)$ we write $A^{\rightarrow}, A^{\uparrow}$ to denote $A \cap \delta^{\rightarrow}(u), A \cap \delta^{\uparrow}(u)$ respectively. Note that $E^{\rightarrow}(S) \subseteq E(S)$ includes only edges between atoms of S and not all edges between vertices in S.

5 Probabilistic statements

5.1 Gurvits' Machinery and Generalizations

The following is the main result of this subsection.

Proposition 5.1. Given a SR distribution $\mu: 2^{[n]} \to \mathbb{R}_+$, let A_1, \ldots, A_m be random variables corresponding to the number of elements sampled from m disjoint sets, and let integers $n_1, \ldots, n_m \ge 0$ be such that for any $S \subseteq [m]$,

$$\mathbb{P}\left[\sum_{i \in S} A_i \ge \sum_{i \in S} n_i\right] \ge \epsilon,$$

$$\mathbb{P}\left[\sum_{i \in S} A_i \le \sum_{i \in S} n_i\right] \ge \epsilon,$$

it follows that,

$$\mathbb{P}\left[\forall i: A_i = n_i\right] \geq f(\epsilon)\mathbb{P}\left[A_1 + \cdots + A_m = n_1 + \cdots + n_m\right],$$

where
$$f(\epsilon) \geq \epsilon^{2^m} \prod_{k=2}^m \frac{1}{\max\{n_k, n_1 + \dots + n_{k-1}\} + 1}$$

We remark that in applications of the above statement, it is enough to know that for any set $S \subseteq [m]$, $\sum_{i \in S} n_i - 1 < \mathbb{E}\left[\sum_{i \in S} A_i\right] < \sum_{i \in S} n_i + 1$. Because, then by Lemma 2.21 we can prove a lower bound on the probability that $\sum_{i \in S} A_i = \sum_{i \in S} n_i$.

We also remark the above lower bound of $f(\epsilon)$ is not tight; in particular, we expect the dependency on m should only be exponential (not doubly exponential). We leave it as an open problem to find a tight lower bound on $f(\epsilon)$.

Proof. Let \mathcal{E} be the event $A_1 + \cdots + A_m = n_1 + \cdots + n_m$.

$$\mathbb{P}\left[1 \le i \le m : A_i = n_i\right] = \mathbb{P}\left[\mathcal{E}\right] \mathbb{P}\left[A_m = n_m | \mathcal{E}\right] \mathbb{P}\left[A_{m-1} = n_{m-1} | A_m = n_m, \mathcal{E}\right] \\ \dots \mathbb{P}\left[A_2 = n_2 | A_3 = n_3, \dots, S_{A_m} = n_m, \mathcal{E}\right]$$

So, to prove the statement, it is enough to prove that for any $2 \le k \le n$,

$$\mathbb{P}\left[A_{k} = n_{k} | A_{k+1} = n_{k+1}, \dots, A_{m} = n_{m}, \mathcal{E}\right] \ge \epsilon^{2^{m-k+1}} \frac{1}{\max\{n_{k}, n_{1} + \dots + n_{k-1}\} + 1}$$
(14)

By the following Claim 5.2,

$$\mathbb{P}\left[A_{k} \geq n_{k} | A_{k+1} = n_{k+1}, \dots, A_{m} = n_{m}, \mathcal{E}\right] \geq e^{2^{m-k+1}},
\mathbb{P}\left[A_{k} \leq n_{k} | A_{k+1} = n_{k+1}, \dots, A_{m} = n_{m}, \mathcal{E}\right] \geq e^{2^{m-k+1}}.$$

So, (14) simply follows by Lemma 5.3. Now we prove this claim.

Claim 5.2. Let $[k] := \{1, ..., k\}$. For any $2 \le k \le m$, and any set $S \subsetneq [k]$,

$$\mathbb{P}\left[\sum_{i\in S}A_{i}\geq\sum_{i\in S}n_{i}|A_{k+1}=n_{k+1},\ldots,A_{m}=n_{m},\mathcal{E}\right] \geq \epsilon^{2^{m-k+1}},$$

$$\mathbb{P}\left[\sum_{i\in S}A_{i}\leq\sum_{i\in S}n_{i}|A_{k+1}=n_{k+1},\ldots,A_{m}=n_{m},\mathcal{E}\right] \geq \epsilon^{2^{m-k+1}}$$

Proof. We prove by induction. First, notice for k=m the statement holds just by lemma's assumption and Lemma 5.4. Now, suppose the statement holds for k+1. Now, fix a set $S \subseteq [k]$. Let $\overline{S} = [k] \setminus S$. Define $A = \sum_{i \in S} A_i$ and $B = \sum_{i \in \overline{S}} A_i$, and similarly define n_A, n_B . By the induction hypothesis,

$$e^{2^{m-k}} \leq \mathbb{P} [A \leq n_A | A_{k+2} = n_{k+2}, \dots, A_m = n_m, \mathcal{E}]$$

The same statement holds for events $A \ge n_A$, $B \le n_B$, $B \ge n_B$, $A + B \ge n_A + n_B$, $A + B \le n_A + n_B$. Let \mathcal{E}_{k+1} be the event $A_{k+2} = n_{k+2}, \ldots, A_m = n_m$, \mathcal{E} . Then, by Lemma 5.3, $\mathbb{P}\left[A + B = n_A + n_B \middle| \mathcal{E}_{k+1}\right] > 0$. Therefore, by Lemma 5.4,

$$\mathbb{P}\left[A \geq n_A | A + B = n_A + n_B, \mathcal{E}_{k+1}\right], \mathbb{P}\left[A \leq n_A | A + B = n_A + n_B, \mathcal{E}_{k+1}\right] \geq (\epsilon^{2^{m-k}})^2 = \epsilon^{2^{m-k+1}}$$

as desired. Note that here we are using that $A + B = n_A + n_B$ and \mathcal{E}_{k+1} implies that $A_{k+1} = n_{k+1}$.

This finishes the proof of Proposition 5.1

Lemma 5.3. Let $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$ be a d-homogeneous SR distribution. If for an integer $0 \leq k \leq d$, $\mathbb{P}_{S \sim \mu}[|S| \geq k] \geq \epsilon$ and $\mathbb{P}_{\mu}[|S| \leq k] \geq \epsilon$. Then,

$$\mathbb{P}\left[|S| = k\right] \ge \min\left\{\frac{\epsilon}{k+1}, \frac{\epsilon}{d-k+1}\right\}, \\
\mathbb{P}\left[|S| = k\right] \ge \min\left\{p_m, \epsilon \left(1 - \left(\frac{\epsilon}{p_m}\right)^{1/\max\{k, d-k\}}\right)\right\}.$$

where $p_m \leq \max_{0 \leq i \leq d} \mathbb{P}[|S| = i]$ is a lower bound on the mode of |S|.

Proof. Since μ is SR, the sequence s_0, s_1, \ldots, s_d where $s_i = \mathbb{P}\left[|S| = i\right]$ is log-concave and unimodal. So, either the mode is in the interval [0,k] or in [k,d]. We assume the former and prove the lemma; the latter can be proven similarly. First, observe that since $s_k \geq s_{k+1} \geq \cdots \geq s_d$, we get $s_k \geq \epsilon/(d-k+1)$. In the rest of the proof, we show that $s_k \geq \epsilon(1-(\epsilon/p_m)^{1/k})$.

Suppose s_i is the mode. It follows that there is $i \le j \le k-1$ such that $\frac{s_j}{s_{j+1}} \ge \left(\frac{s_i}{s_k}\right)^{1/(k-i)}$. So, by Eq. (6),

$$\epsilon \le s_k + \dots + s_d \le \frac{s_k}{1 - \left(\frac{s_k}{s_i}\right)^{1/(k-i)}}$$

If $s_k \ge p_m$ or $s_k \ge \epsilon$ then we are done. Otherwise,

$$s_k \ge \epsilon \left(1 - (s_k/p_m)^{1/(k-i)}\right) \ge \epsilon \left(1 - (\epsilon/p_m)^{1/k}\right)$$

where we used $s_i \geq p_m$ and $s_k \leq \epsilon$.

Lemma 5.4. Given a strongly Rayleigh distribution $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$, let A, B be two (nonnegative) random variables corresponding to the number of elements sampled from two disjoint sets such that $\mathbb{P}[A+B=n]>0$ where $n=n_A+n_B$. Then,

$$\mathbb{P}\left[A \ge n_A | A + B = n\right] = \mathbb{P}\left[B \le n_B | A + B = n\right] \ge \mathbb{P}\left[A \ge n_A\right] \mathbb{P}\left[B \le n_B\right],\tag{15}$$

$$\mathbb{P}\left[A \le n_A | A + B = n\right] = \mathbb{P}\left[B \ge n_B | A + B = n\right] \ge \mathbb{P}\left[A \le n_A\right] \mathbb{P}\left[B \ge n_B\right]. \tag{16}$$

Proof. We prove the second statement. The first one can be proven similarly. First, notice

$$\mathbb{P}[A \le n_A, A + B \ge n] + \mathbb{P}[B \ge n_B, A + B < n]
= \mathbb{P}[B \ge n_B, A \le n_A, A + B \ge n] + \mathbb{P}[A \le n_A, B \ge n_B, A + B < n]
= \mathbb{P}[B \ge n_B, A \le n_A] \ge \mathbb{P}[B \ge n_B] \mathbb{P}[A \le n_A] =: \alpha,$$

where the last inequality follows by negative association. Say $q = \mathbb{P}[A + B \ge n]$. From above, either $\mathbb{P}[A \le n_A, A + B \ge n] \ge \alpha q$ or $\mathbb{P}[B \ge n_B, A + B < n] \ge \alpha (1 - q)$. In the former case, we get $\mathbb{P}[A \le n_A | A + B \ge n] \ge \alpha$ and in the latter we get $\mathbb{P}[B \ge n_B | A + B < n] \ge \alpha$. Now the lemma follows by the stochastic dominance property

$$\mathbb{P}\left[A \le n_A | A + B = n\right] \ge \mathbb{P}\left[A \le n_A | A + B \ge n\right]$$

$$\mathbb{P}\left[B \ge n_B | A + B = n\right] \ge \mathbb{P}\left[B \ge n_B | A + B < n\right]$$

Note that in the special case that A + B < n never happens, the lemma holds trivially.

Combining the previous two lemmas, we get

Corollary 5.5. Let $\mu: 2^{[n]} \to \mathbb{R}_{\geq 0}$ be a SR distribution. Let A, B be two random variables corresponding to the number of elements sampled from two disjoint sets of elements. If $\mathbb{P}\left[A \geq n_A\right]$, $\mathbb{P}\left[B \geq n_B\right] \geq \epsilon_1$ and $\mathbb{P}\left[A \leq n_A\right]$, $\mathbb{P}\left[B \leq n_B\right] \geq \epsilon_2$, then

$$\mathbb{P}\left[A = n_{A}|A + B = n_{A} + n_{B}\right] \ge \epsilon \min\left\{\frac{1}{n_{A} + 1}, \frac{1}{n_{B} + 1}\right\},
\mathbb{P}\left[A = n_{A}|A + B = n_{A} + n_{B}\right] \ge \min\left\{p_{m}, \epsilon(1 - (\epsilon/p_{m})^{1/\max\{n_{A}, n_{B}\}})\right\}$$

where $\epsilon = \epsilon_1 \epsilon_2$ and $p_m \leq \max_{0 \leq k \leq n_A + n_B} \mathbb{P}[A = k | A + B = n_A + n_B]$ is a lower bound on the mode of A.

For $n_A=1$, $n_B=1$, if $\mathbb{P}\left[A=1|A+B=2\right] \leq \epsilon$, since the distribution of A is unimodal, we get $p_m \geq 1-2\epsilon$. Therefore, if $\epsilon \leq 1/3$,

$$\mathbb{P}\left[A=1|A+B=2\right] \geq \max\left\{\epsilon/2, \epsilon\left(1-\frac{\epsilon}{1-2\epsilon}\right)\right\}.$$

5.2 Max Flow

The following proposition is the main statement of this subsection.

Proposition 5.6. Let $\mu: 2^E \to \mathbb{R}_{\geq 0}$ be a homogeneous SR distribution. For any $300\epsilon < \zeta < 0.003$ and disjoint sets $A, B \subseteq E$ such that $1 - \epsilon \leq \mathbb{E}[A_T]$, $\mathbb{E}[B_T] \leq 1 + \epsilon$ (where $T \sim \mu$) there is an event $\mathcal{E}_{A,B}(T)$ such that $\mathbb{P}[\mathcal{E}_{A,B}(T)] \geq 0.002\zeta^2(1 - \zeta/3 - \epsilon)$ and it satisfies the following three properties.

- *i*) $\mathbb{P}[A_T = B_T = 1 | \mathcal{E}_{A,B}(T)] = 1$,
- ii) $\sum_{e \in A} |\mathbb{P}[e] \mathbb{P}[e|\mathcal{E}_{A,B}(T)]| \leq \zeta$, and
- iii) $\sum_{e \in B} |\mathbb{P}[e] \mathbb{P}[e|\mathcal{E}_{A,B}(T)]| \leq \zeta$.

In other words, under event $\mathcal{E}_{A,B}$ which has a constant probability, $A_T = B_T = 1$ and the marginals of all edges in A, B are preserved up to total variation distance ζ . We also remark that above statement holds for a much larger value of ζ at the expense of a smaller lower bound on $\mathbb{P}\left[\mathcal{E}_{A,B}(T)\right]$.

Before, proving the above statement we prove the following lemma.

Lemma 5.7. Let $\mu: 2^E \to \mathbb{R}_{\geq 0}$ be a homogeneous SR distribution. Let $A, B \subseteq E$ be two disjoint sets such that $1 - \epsilon \leq \mathbb{E}\left[A_T\right]$, $\mathbb{E}\left[B_T\right] \leq 1 + \epsilon$ (where $T \sim \mu$), $A' \subset A$ and $B' \subseteq B$ and $\mathbb{E}\left[A'_T \cup B'_T\right] \geq 1 + \alpha$ for some $\alpha > 100\epsilon$. If $\alpha < 0.001$, we have

$$\mathbb{P}\left[A_T' = B_T' = A_T = B_T = 1\right] \ge 0.1\alpha^3.$$

Proof. First, condition on $(A \setminus A')_T = (B \setminus B')_T = 0$. This happens with probability at least $\alpha - 2\epsilon \geq 0.98\alpha$ because $\mathbb{E}\left[A_T\right] + \mathbb{E}\left[B_T\right] \leq 2 + 2\epsilon$ and $\mathbb{E}\left[A'_T\right] + \mathbb{E}\left[B'_T\right] \geq 1 + \alpha$. Call this measure ν . It follows by negative association that

$$\mathbb{E}_{\nu}\left[A_{T}^{\prime}\right], \mathbb{E}_{\nu}\left[B_{T}^{\prime}\right] \in \left[\alpha - \epsilon, 2 + 3\epsilon - \alpha\right]. \tag{17}$$

• Case 1: $\mathbb{E}_{\nu} [A'_T + B'_T] > 1.5$. Since $\mathbb{E}_{\nu} [A'_T + B'_T] \le 2 + 2\epsilon$, by Lemma 2.21, $\mathbb{P}_{\nu} [A'_T + B'_T = 2] \ge 0.25$. Furthermore, by ,

$$\begin{split} \mathbb{P}_{\nu}\left[A_{T}' \geq 1\right], \mathbb{P}_{\nu}\left[B_{T}' \geq 1\right] \geq 1 - e^{-(\alpha - \epsilon)} \geq 0.98\alpha & \text{(Lemma 2.22, } \alpha < 0.001) \\ \mathbb{P}_{\nu}\left[A_{T}' \leq 1\right], \mathbb{P}_{\nu}\left[B_{T}' \leq 1\right] \geq \alpha/2 - 1.5\epsilon & \text{(Markov's Inequality)} \end{split}$$

Therefore, by Corollary 5.5 and using $\alpha \leq 0.001$, $\mathbb{P}\left[A_T' = 1 | A_T' + B_T' = 2\right] \geq 0.45\alpha^2$. It follows that

$$\mathbb{P}\left[A_T = B_T = A_T' = B_T' = 1\right] \ge (0.98\alpha)\mathbb{P}_{\nu}\left[A_T' = B_T' = 1\right] \ge (0.98\alpha)0.25(0.45\alpha^2) \ge 0.1\alpha^3.$$

• Case 2: $\mathbb{E}\left[A_T' + B_T'\right] \le 1.5$ Since $\mathbb{E}_{\nu}\left[A_T' + B_T'\right] \ge 1 + \alpha$, by Lemma 2.21, $\mathbb{P}\left[A_T' + B_T' = 2\right] \ge \alpha e^{-\alpha} \ge 0.99\alpha$. But now $\mathbb{E}\left[A_T'\right]$, $\mathbb{E}\left[B_T'\right] \le 1.5$ and therefore by Markov's Inequality,

$$\mathbb{P}_{
u}\left[A_T'\leq 1
ight]$$
 , $\mathbb{P}_{
u}\left[B_T'\leq 1
ight]\geq 0.25$.

On the other hand, by Lemma 2.22 $\mathbb{P}_{\nu}[A'_T \geq 1]$, $\mathbb{P}_{\nu}[B'_T \geq 1] \geq (\alpha - \epsilon)e^{-\alpha + \epsilon} \geq 0.96\alpha$. It follows by Corollary 5.5 that $\mathbb{P}[A'_T = 1|A'_T + B'_T = 2] \geq 0.2\alpha$. Therefore,

$$\mathbb{P}\left[A_T = B_T = A_T' = B_T' = 1\right] \ge (0.98\alpha)\mathbb{P}_{\nu}\left[A_T' = B_T' = 1\right] \ge (0.98\alpha)(0.2\alpha)(0.99\alpha) \ge 0.1\alpha^3$$
 as desired.

It is worth noting that α^3 dependency is necessary in the above example. For an explicit Strongly Rayleigh distribution consider the following product distribution:

$$(\alpha x_1 + (1 - \alpha)y_2)(\alpha y_1 + (1 - \alpha)z_2)(\alpha z_1 + (1 - \alpha)x_2),$$

and let $A = \{x_1, x_2\}$, $B' = B = \{y_1, y_2\}$, and $A' = \{x_1\}$. Observe that

$$\mathbb{P}[A = B = A' = B' = 1] = \mathbb{P}[x_1 = 1, y_1 = 1, z_1 = 1] = \alpha^3.$$

Proof of Proposition 5.6. To prove the lemma, we construct an instance of the max-flow, min-cut problem. Consider the following graph with vertex set $\{s,A,B,t\}$. For any $e \in A$, $f \in B$ connect e to f with a directed edge of capacity $y_{e,f} = \mathbb{P}\left[e,f \in T|A_T = B_T = 1\right]$. For any $e \in E$, let $x_e := \mathbb{P}\left[e \in T\right]$. Connect s to $e \in A$ with an arc of capacity βx_e and similarly connect $f \in B$ to t with arc of capacity βx_f , where β is a parameter that we choose later. We claim that the min-cut of this graph is at least $\beta(1-e-\zeta/3)$. Assuming this, we can prove the lemma as follows: let \mathbf{z} be the maximum flow, where $z_{e,f}$ is the flow on the edge from e to f. We define the event $\mathcal{E}_{A,B}(T) = \mathcal{E}(T)$ to be the union of events $z_{e,f}$. More precisely, conditioned on $A_T = B_T = 1$ the events $e, f \in T|A_T = B_T = 1$ are disjoint for different pairs $e \in A$, $f \in B$, so we know that we have a specific e, f in the tree T with probability $y_{e,f}$. And, of course, $\sum_{e \in A, f \in B} y_{e,f} = 1$. So, for $e \in A$, $f \in B$ we include a $z_{e,f}$ measure of trees, T, such that $A_T = B_T = 1$, $e, f \in T$. First, observe that

$$\mathbb{P}\left[\mathcal{E}\right] = \sum_{e \in A, f \in B} z_{e, f} \mathbb{P}\left[A_T = B_T = 1\right] \ge \beta (1 - \zeta/3 - \epsilon) \mathbb{P}\left[A_T = B_T = 1\right]. \tag{18}$$

Part (i) of the proposition follows from the definition of \mathcal{E} . Now, we check part (ii): Say $z = \sum_{e \in A, f \in B} z_{e,f}$, and the flow into e is z_e . Then,

$$\sum_{e \in A} |x_e - \mathbb{P}\left[e \in T | \mathcal{E}\right]| = \sum_{e \in A} \left| x_e - \sum_f \frac{z_{e,f}}{z} \right| = \sum_{e \in A} |x_e - \frac{z_e}{z}|$$

Note that both x and z_e/z define a probability distribution on edges in A; so the RHS is just the total variation distance between these two distributions. We can write

$$\begin{split} \sum_{e \in X} |x_e - \mathbb{P}\left[e \in T | \mathcal{E}\right]| &= 2 \sum_{e \in X: z_e/z > x_e} \left(\frac{z_e}{z} - x_e\right) \\ &\leq 2 \sum_{e \in X: z_e/z > x_e} \left(\frac{\beta x_e}{\beta (1 - \zeta/3 - \epsilon)} - x_e\right) \\ &\leq 2 \cdot \sum_{e \in X: z_e/z > x_e} \frac{\zeta/3 + \epsilon}{1 - \zeta/3 - \epsilon} \leq 2 \frac{(1 + \epsilon)(\zeta/3 + \epsilon)}{1 - \zeta/3 - \epsilon} \leq \zeta. \end{split}$$

The first inequality uses that the max-flow is at least $\beta(1-\zeta/3)$ and that the incoming flow of e is at most βx_e , and the last inequality follows by $\zeta < 1/20$ and $\epsilon < \zeta/300$. (iii) can be checked similarly.

It remains to lower-bound the max-flow or equivalently the min-cut. Consider an s, t-cut S, \overline{S} , i.e., assume $s \in S$ and $t \notin S$. Define $S_A = A \cap S$ and $S_B = B \cap S$. We write

$$cap(S, \overline{S}) = \beta x(\overline{S}_A) + \beta x(S_B) + \sum_{e \in S_A, f \in \overline{S}_B} y_{e,f}$$
$$= \beta x(\overline{S}_A \cup S_B) + \mathbb{P} \left[S_A = \overline{S}_B = 1 | A = B = 1 \right]$$

If $x(S_B) \ge x(S_A) - \zeta/3$, then

$$\operatorname{cap}(S,\overline{S}) \ge \beta x(\overline{S}_A \cup S_B) \ge \beta (x(\overline{S}_A \cup S_A) - \zeta/3) \ge \beta (1 - \epsilon - \zeta/3),$$

and we are done. Otherwise, say $x(S_B) + \gamma = x(S_A)$, for some $\gamma > \zeta/3$. So,

$$x(\overline{S}_B) + x(S_A) = x(\overline{S}_B) + x(S_B) + \gamma \ge 1 - \epsilon + \gamma$$

So, by Lemma 5.7 with $(\alpha = \gamma - \epsilon)$

$$\mathbb{P}\left[S_A = \overline{S}_B = 1 | A = B = 1\right] \ge \frac{\mathbb{P}\left[S_A = \overline{S}_B = A = B = 1\right]}{\mathbb{P}\left[A = B = 1\right]} \ge \frac{0.1(\gamma - \epsilon)^3}{\mathbb{P}\left[A = B = 1\right]}.$$

It follows that

$$cap(S,\overline{S}) \geq \beta x(\overline{S}_A \cup S_B) + \frac{0.1(\gamma - \epsilon)^3}{\mathbb{P}[A = B = 1]}$$

$$\geq \beta(x(\overline{S}_A \cup S_A) - \gamma) + \frac{0.1(\gamma - \epsilon)^3}{\mathbb{P}[A = B = 1]}$$

$$\geq \beta(1 - \epsilon - \gamma) + \frac{0.1(\gamma - \epsilon)^3}{\mathbb{P}[A = B = 1]}$$

To prove the lemma we just need to choose β such that RHS is at least $\beta(1 - \epsilon - \zeta/3)$. Or equivalently,

$$\frac{0.1(\gamma - \epsilon)^3}{\mathbb{P}[A = B = 1]} \ge \beta(\gamma - \zeta/3).$$

In other words, it is enough to choose $\beta \leq \frac{0.1(\gamma - \epsilon)^3}{\mathbb{P}[A = B = 1](\gamma - \zeta/3)}$. Since $\gamma \geq \zeta/3$ and $\zeta/3 > 100\epsilon$, we certainly have $\gamma - \epsilon \geq \zeta/6$. Therefore, we can set $\beta = \frac{0.1\zeta^2/6^2}{\mathbb{P}[A = B = 1]}$. Finally, this plus (18) gives

$$\mathbb{P}\left[\mathcal{E}\right] \ge (1 - \zeta/3 - \epsilon)\beta\mathbb{P}\left[A = B = 1\right] = 0.1(\zeta^2/6^2)(1 - \zeta/3 - \epsilon) \ge 0.002\zeta^2(1 - \zeta/3 - \epsilon)$$
 as desired.

Definition 5.8 (Max-flow Event). For a polygon cut $S \in \mathcal{H}$ with polygon partition A, B, C, let v be the max-entropy distribution conditioned on S is a tree and $C_T = 0$. By Lemma 2.23, we can write $v : v_S \times v_{G/S}$, where v_S is supported on trees in E(S) and $v_{G/S}$ on trees in E(G/S). For a sample $(T_S, T_{G/S}) \sim v_S \times v_{G/S}$, we say \mathcal{E}_S occurs if $\mathcal{E}_{A,B}(T_{G/S})$ occurs, where $\mathcal{E}_{A,B}(.)$ is the event defined in Proposition 5.6 for sets A, B and $\zeta = \varepsilon_M := \frac{1}{4000}$ and $\varepsilon = 2\varepsilon_\eta$.

Corollary 5.9. For a polygon cut $S \in \mathcal{H}$ with polygon partition A, B, C, we have,

- i) $\mathbb{P}\left[\mathcal{E}_S\right] \geq 0.001\epsilon_M^2$.
- ii) For any set $F \subseteq \delta(S)$ conditioned on \mathcal{E}_S marginals of edges in F are preserved up to $\epsilon_M + \epsilon_\eta$ in total variation distance.
- iii) For any $F \subseteq E(S) \cup \delta(S)$ where either $F \cap A = \emptyset$ or $F \cap B = \emptyset$, there is some $q \in x(F) \pm (\epsilon_M + 2\epsilon_n)$ such that the law of $F_T | \mathcal{E}_S$ is the same as a BS(q).

Proof. Condition S to be a tree and $C_T = 0$ and let ν be the resulting measure. It follows that

$$\mathbb{P}\left[\mathcal{E}_S\right] = \mathbb{P}_{\nu}\left[\mathcal{E}_S\right] \mathbb{P}\left[C_T = 0, S \text{ tree}\right] \ge 0.002 \varepsilon_M^2 (1 - \varepsilon_M/3 - \varepsilon) \mathbb{P}\left[C_T = 0, S \text{ tree}\right] \ge 0.001 \varepsilon_M^2.$$

which proves (i).

Now, we prove (ii). By Proposition 5.6, the marginals of edges in $\delta(S)$ are preserved up to a total variation distance of ϵ_M , so

$$\mathbb{E}_{\nu}\left[(F \cap \delta(S))_T | \mathcal{E}_{A,B}(T_{G/S})\right] = \mathbb{E}_{\nu}\left[(F \cap \delta(S))_T\right] \pm \epsilon_M.$$

Since $x(C) \le \epsilon_{\eta}$ and $x(\delta(S)) \le 2 + \epsilon_{\eta}$, by negative association,

$$x(F \cap \delta(S)) - \epsilon_{\eta}/2 \le \mathbb{E}_{\nu} [(F \cap \delta(S))_T] \le x(F \cap \delta(S)) + \epsilon_{\eta}.$$

This proves (ii). Also observe that since conditioned on \mathcal{E}_S , we choose at most one edge of $F \cap \delta(S)$, $(F \cap \delta(S))_T$ is a $BS(q_{G/S})$ for some $q_{G/S} = x(F) \pm (\epsilon_M + \epsilon_\eta)$.

On the other hand, observe that conditioned on \mathcal{E}_S , S is a tree, so

$$x(F \cap E(S)) \leq \mathbb{E}\left[(F \cap E(S))_T | \mathcal{E}_S\right] \leq x(F \cap E(S)) + \epsilon_n/2.$$

Since the distribution of $(F \cap E(S))_T$ under $\nu | \mathcal{E}_S$ is SR, there is a random variable $BS(q_S) = (F \cap E(S))_T$ where $x(F \cap E(S)) \leq q_S \leq x(F \cap E(S)) + \epsilon_{\eta}/2$.

Finally,
$$F_T | \mathcal{E}_S$$
 is exactly $BS(q_S) + BS(q_{G/S}) = BS(q)$ for $q = x(F) \pm (\epsilon_M + 2\epsilon_\eta)$.

Corollary 5.10. For $u \in \mathcal{H}$ and a polygon cut $S \in \mathcal{H}$ that is an ancestor of u,

$$\mathbb{P}\left[\delta(u)_T \ odd | \mathcal{E}_S\right] \leq 0.5678.$$

Proof. First, notice by Observation 4.32, $\delta(u) \cap \delta(S)$ is either a subset of A, B, or C. Therefore, we can write $\delta(u)_T | \mathcal{E}_S$ as a BS(q) for $q \in 2 \pm [0.001]$ (where we use that $\epsilon_M + 3\epsilon_\eta < 0.001$). Furthermore, since $\delta(u)_T \neq 0$ with probability 1, we can write this as a 1 + BS(q - 1). Therefore, by Corollary 2.17,

$$\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{E}_S\right] = \mathbb{P}\left[BS(q-1) \text{ even}\right] \le \frac{1}{2}(1 + e^{-2(q-1)}) \le \frac{1}{2}(1 + e^{-1.999}) \le 0.5678$$

as desired. \Box

Corollary 5.11. For a polygon cut $u \in \mathcal{H}$ and a polygon cut $S \in \mathcal{H}$ that is an ancestor of u,

$$\mathbb{P}\left[u \text{ not left happy}|\mathcal{E}_S\right] \leq 0.56794.$$

and the same follows for right happy.

Proof. Let A, B, C be the polygon partition of u. Recall that for u to be left-happy, we need $C_T = 0$ and A_T odd. Similar to the previous statement, we can write $A_T | \mathcal{E}_S$ as a $BS(q_A)$ for $q_A \in 1 \pm [0.00026]$ (where we used that $\epsilon_M = 1/4000$ and $\epsilon_\eta \leq \epsilon_M/300$). Therefore, by Corollary 2.17,

$$\mathbb{P}\left[A_T \text{ even}|\mathcal{E}_S\right] \le \frac{1}{2}(1 + e^{-2q_A}) \le \frac{1}{2}(1 + e^{-1.9997}) \le 0.56768$$

Finally, $\mathbb{E}\left[C_T | \mathcal{E}_S\right] \leq x(C_T) + \epsilon_M + 2\epsilon_\eta \leq 0.00026$. Now using the union bound,

$$\mathbb{P}[u \text{ not left happy } | \mathcal{E}_S] \le 0.56768 + 0.00026 \le 0.56794$$

as desired.

5.3 Good Edges

Definition 5.12 (Half Edges). We say an edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ in a degree cut $S \in \mathcal{H}$, i.e., $p(\mathbf{e}) = S$, is a half edge if $|x_{\mathbf{e}} - 1/2| \le \epsilon_{1/2}$.

Definition 5.13 (Good Edges). We say a top edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ in a degree cut $S \in \mathcal{H}$ is (2-2) good, if one of the following holds:

- 1. **e** is not a half edge or
- 2. **e** is a half edge and $\mathbb{P}\left[\delta(u)_T = \delta(v)_T = 2|u,v \text{ trees}\right] \geq 3\epsilon_{1/2}$.

We say a top edge \mathbf{e} is bad otherwise. We say every bottom edge bundle is good (but generally do not refer to bottom edges as good or bad). We say any edge \mathbf{e} that is a neighbor of u_0 or v_0 is bad.

In the next subsection we will see that for any top edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ which is not a half edge, $\mathbb{P}\left[(\delta(u))_T = (\delta(v))_T = 2|u,v|\text{ trees}\right] = \Omega(1)$. The following theorem is the main result of this subsection:

Theorem 5.14. For $\epsilon_{1/2} \leq 0.0005$, $\epsilon_{\eta} \leq \epsilon_{1/2}^2$, a top edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ is bad only if the following three conditions hold simultaneously:

- e is a half edge,
- $x(\delta^{\uparrow}(u)), x(\delta^{\uparrow}(v)) < 1/2 + 9\epsilon_{1/2}$
- Every other half edge bundle incident to u or v is (2-2) good.

The proof of this theorem follows from Lemma 5.16 and Lemma 5.17 below.

In this subsection, we use repeatedly that for any atom u in a degree cut S, $x(\delta(u)) \le 2 + \epsilon_{\eta}$. We also repeatedly use that for a half edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ in a degree cut, conditioned on u, v trees, \mathbf{e} is in or out with probability at least $1/2 - \epsilon_{1/2} - 3\epsilon_{\eta} > 0.49$.

Lemma 5.15. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a good half edge bundle in a degree cut $S \in \mathcal{H}$. Let $A = \delta(u)_{-\mathbf{e}}$ and $B = \delta(v)_{-\mathbf{e}}$. If $\epsilon_{1/2} \leq 0.001$ and $\epsilon_{\eta} < \epsilon_{1/2}/100$, then

$$\mathbb{P}\left[A_T + B_T \le 2|u,v \; trees\right], \mathbb{P}\left[A_T + B_T \ge 4|u,v \; trees\right] \ge 0.4\epsilon_{1/2}$$

Proof. Throughout the proof all probabilistic statements are with respect to the measure μ conditioned on u,v trees. Let $p_{\leq 2} = \mathbb{P}\left[A_T + B_T \leq 2\right]$ and similarly define $p_{\geq 4}$. Observe that whenever $\delta(u)_T = \delta(v)_T = 2$, we must have $A_T + B_T \neq 3$. Since **e** is 2-2 good, this event happens with probability at least $3\epsilon_{1/2}$, i.e.,

$$p_{\leq 2} + p_{>4} \geq 3\epsilon_{1/2} \tag{19}$$

By Lemma 2.21, using the fact that $p_0 = 0$, we get $p_{-3} \ge 1/4$.

First, we show that $p_{\leq 2} \geq 0.4\epsilon_{1/2}$. We have

$$3 + 2\epsilon_{1/2} \ge \mathbb{E}\left[A_T + B_T\right] \ge 4p_{\ge 4} + 2p_{=2} + 3(1 - p_{\ge 4} - p_{\le 2}) = 3 + p_{\ge 4} - p_{=2} - 3p_{=1}.$$

Again, we are using $p_0 = 0$. By log-concavity $p_{-2}^2 \ge p_{-3}p_{-1}$, so since $p_{-3} \ge 1/4$, $p_{-1} \le 4p_{-2}^2 \le 4p_{-2}^2$. Therefore,

$$p_{\geq 4} - 2\epsilon_{1/2} \leq p_{=2} + 3p_{=1} = p_{\leq 2} + 2p_{=1} \leq p_{\leq 2}(1 + 8p_{\leq 2}).$$

Finally, since $\epsilon_{1/2} < 0.001$, plugging this upper bound on $p_{\geq 4}$ into Eq. (19) we get $p_{\leq 2} \geq 0.4\epsilon_{1/2}$.

Now, we show $p_{\geq 4} \geq 0.4\epsilon_{1/2}/2$. Assume $p_{\geq 4} < \epsilon_{1/2}/2$ (otherwise we are done). Since $p_{=3} \geq 1/4$ by Lemma 2.18 with $\gamma \leq (\epsilon_{1/2}/2)/(1/4) = 2\epsilon_{1/2}$

$$\mathbb{E}\left[A_T + B_T | A_T + B_T \ge 4\right] \cdot p_{\ge 4} \le \frac{p_{\ge 4}}{1 - 2\epsilon_{1/2}} (4 + 3\epsilon_{1/2})$$

Therefore,

$$3 - 2\epsilon_{1/2} - 2\epsilon_{\eta} \le \mathbb{E}\left[A_T + B_T\right] \le 2p_{\le 2} + \frac{p_{\ge 4}}{1 - 2\epsilon_{1/2}} (4 + 3\epsilon_{1/2}) + 3(1 - p_{\le 2} - p_{\ge 4})$$

So, $1.01p_{\geq 4} \geq p_{\leq 2} - 2.02\epsilon_{1/2}$ where we used $\epsilon_{1/2} \leq 0.001$ and $\epsilon_{\eta} < \epsilon_{1/2}/100$. Now, $p_{\geq 4} \geq 0.4\epsilon_{1/2}$ follows by Eq. (19).

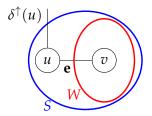

Figure 11: Setting of Lemma 5.16

Lemma 5.16. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a half edge bundle in a degree cut $S \in \mathcal{H}$, and suppose $x(\delta^{\uparrow}(u)) \ge 1/2 + k\epsilon_{1/2}$. If $k \ge 9$ and $\epsilon_{1/2} \le 0.001$, then, \mathbf{e} is 2-2 good.

Proof. First, condition u, v, S to be trees. Let $W = S \setminus \{u\}$. Since S is a near mincut,

$$x(\delta(W)) = x(\delta(S)) + x(\delta(u)) - 2x(\delta^{\uparrow}(u)) \le 2(2 + \epsilon_{\eta}) - 2(1/2 + k\epsilon_{1/2}) = 3 - 2k\epsilon_{1/2} + 2\epsilon_{\eta}$$

So, by Lemma 2.23, $\mathbb{P}[W \text{ is tree}] \ge 1/2 + k\epsilon_{1/2} - \epsilon_{\eta} - \epsilon_{\eta}$. Note that the extra $-\epsilon_{\eta}$ comes from the fact that conditioning u be a tree can decrease marginals of edges in E(W) by at most ϵ_{η} .

Let ν be the measure in which we also condition on W to be a tree. Note that ν is a strongly Rayleigh distribution on the set of edges in $E(W) \cup E(u,W) \cup E(G/S)$; this is because ν is a product of 3 SR distributions each supported on one of the aforementioned sets.

Let $X = \delta^{\uparrow}(u)_T$ and $Y = \delta(v)_T - 1$. Observe that, under v, X = Y = 1 iff $\delta(u)_T = \delta(v)_T = 2$. Furthermore, $Y \ge 0$ with probability 1, since v is connected to the rest of the graph. So, we just to lower $\mathbb{P}_v[X = Y = 1]$. First, notice

$$\mathbb{E}_{\nu}\left[X\right] \in \left[0.5 + k\epsilon_{1/2} - \epsilon_{\eta}, 1 + \epsilon_{\eta}\right] \\ \mathbb{E}_{\nu}\left[Y\right] \in \left[0.5 + k\epsilon_{1/2} - 4\epsilon_{\eta}, 1.5 - k\epsilon_{1/2} + 3\epsilon_{\eta}\right]$$
(20)

Note that using Proposition 5.1, we can immediately argue that $\mathbb{P}_{\nu}[X = Y = 1] \geq \Omega(\epsilon_{1/2})$. We do the following more refined analysis to make sure that this probability is at least $3\epsilon_{1/2}$ (for $\epsilon_{1/2} \leq 0.0005$) and $k \geq 9$.

Case 1: $\mathbb{P}_{\nu}[X+Y=2] \geq 0.05$. By Lemma 2.22, $\mathbb{P}_{\nu}[X\geq 1] \mathbb{P}_{\nu}[Y\geq 1] \geq 1-e^{-0.5} \geq 0.4$. On the other hand, by Markov $\mathbb{P}_{\nu}[X\leq 1]$, $\mathbb{P}_{\nu}[Y\leq 1] \geq 1/4$. Therefore, by Corollary 5.5, $\mathbb{P}_{\nu}[X=1|X+Y=2] \geq 0.1(1-1/8) = 0.0875$. Therefore $\mathbb{P}_{\nu}[X=1,Y=1] \geq (0.05)(0.087) \geq 0.004$. Finally, removing the conditioning on S and W being trees, we get $\mathbb{P}[X=1,Y=1] \geq (0.5)(0.004) = 0.002 \geq 3\epsilon_{1/2}$ since $\epsilon_{1/2} \leq 0.0005$.

Case 2: $\mathbb{P}_{\nu}[X + Y = 2] < 0.05$. We know that $\mathbb{E}_{\nu}[X + Y] \leq 2.5$; so if it is also at least 1.2, then $\mathbb{P}[X + Y = 2] \geq 0.05$ by Lemma 2.21.

So, from now on assume $\mathbb{E}_{\nu}[X+Y] < 1.2$. Now, by Lemma 2.21, $\mathbb{P}[X+Y=1] \ge 0.25$. So, since $\mathbb{P}_{\nu}[X+Y=2] < 0.05$, by Lemma 2.18 (with $\gamma = 0.2, i = 1, k = 3$), $\mathbb{P}[X+Y>2] < 0.02$.

On the other hand, by Eq. (20), since $\mathbb{E}_{\nu}[X+Y]<1.2$, we have $\mathbb{E}_{\nu}[X]$, $\mathbb{E}_{\nu}[Y]\leq0.7$ (since each of them is at least 0.5 by (20)). It follows by Lemma 2.22 that $\mathbb{P}_{\nu}[X\geq1]$, $\mathbb{P}_{\nu}[Y\geq1]\geq1-e^{-0.7}\geq0.5$. In this case, applying stochastic dominance, we have

$$\begin{split} \mathbb{P}_{\nu} \left[X \geq 1 | X + Y = 2 \right] & \geq \mathbb{P}_{\nu} \left[X \geq 1 | X + Y \leq 2 \right] \\ & \geq \mathbb{P}_{\nu} \left[X \geq 1, X + Y \leq 2 \right] \\ & \geq \mathbb{P}_{\nu} \left[X \geq 1 \right] - \mathbb{P}_{\nu} \left[X + Y > 2 \right] \geq \mathbb{P}_{\nu} \left[X \geq 1 \right] - 0.02 \geq 0.48. \end{split}$$

Similarly, $\mathbb{P}[X \le 1|X+Y=2] = \mathbb{P}[Y \ge 1|X+Y=2] \ge \mathbb{P}[Y \ge 1] - 0.02 \ge 0.48$. Finally since the distribution of X conditioned on X+Y=2 is the same as the number of successes in 2 independent Bernoulli trials, with probabilities, say, p_1 and p_2 , we can minimize $p_1(1-p_2) + (1-p_1)p_2$ subject to $1-p_1p_2 \ge 0.48$ and $1-(1-p_1)(1-p_2) \ge 0.48$. Solving this yields $\mathbb{P}[X=1|X+Y=2] \ge 0.4$.

Lastly, observe that since by Eq. (20) $\mathbb{E}_{\nu}[X+Y] \ge 1 + (2k-1)\epsilon_{1/2}$, by Lemma 2.21 we can write

$$\mathbb{P}_{\nu}[X+Y=2] \ge (2k-1)\epsilon_{1/2}e^{-(2k-1)\epsilon_{1/2}} \ge (2k-2)\epsilon_{1/2}.$$

Finally,

$$\mathbb{P}\left[\delta(u)_T = \delta(v)_T = 2\right] \ge \mathbb{P}\left[W \text{ tree}\right] \mathbb{P}_{\nu}\left[X = 1|X + Y = 2\right] \mathbb{P}_{\nu}\left[X + Y = 2\right] \ge 0.5 \cdot 0.4(2k - 2)\epsilon_{1/2}$$

To get the RHS to be at least $3\epsilon_{1/2}$ it suffices that $k \geq 9$.

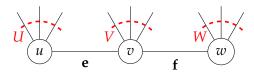

Figure 12: Setting of Lemma 5.17

Lemma 5.17. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$, $\mathbf{f} = (\mathbf{v}, \mathbf{w})$ be two half edge bundles in a degree cut $S \in \mathcal{H}$. If $\epsilon_{1/2} < 0.0005$, then one of \mathbf{e} or \mathbf{f} is good.

Proof. We use the following notation $V = \delta(v)_{-\mathbf{e}-\mathbf{f}}$, $U = \delta(u)_{-\mathbf{e}}$, $W = \delta(w)_{-\mathbf{f}}$. For a set A of edges and an edge bundle \mathbf{e} we write $A_{+\mathbf{e}} = A \cup \{\mathbf{e}\}$. Furthermore, for a measure ν we write $\nu_{-\mathbf{e}}$ to denote ν conditioned on $\mathbf{e} \notin T$.

Condition u, v, w to be trees. This occurs with probability at least $1 - 3\epsilon_{\eta}$. Let ν be this measure. By Lemma 2.27, without loss of generality, we can assume

$$\mathbb{E}_{\nu}\left[W_{T}|\mathbf{e} \notin T\right] \leq \mathbb{E}_{\nu}\left[W_{T}\right] + 0.405. \tag{21}$$

Now, if $\mathbb{E}_{\nu}[V_T|\mathbf{e} \notin T] \geq \mathbb{E}_{\nu}[V_T] + 0.03$, then we will show \mathbf{e} is 2-2 good. First,

$$\mathbb{E}_{\nu_{-\mathbf{e}}} [(V_{+\mathbf{f}})_T] \in [1.53 - \epsilon_{1/2}, 2 + \epsilon_{\eta}],$$

$$\mathbb{E}_{\nu_{-\mathbf{e}}} [U_T] \in [1.5 - \epsilon_{1/2}, 2 + \epsilon_{\eta}],$$

$$\mathbb{E}_{\nu_{-\mathbf{e}}} [(V_{+\mathbf{f}})_T + U_T] \in [3.03 - 2\epsilon_{1/2}, 3.5 + 3\epsilon_{1/2}].$$

Therefore, by Lemma 2.21, $\mathbb{P}_{\nu_{-e}}[(V_{+f})_T + U_T = 4] \ge 0.029$, where we use the fact that $U_T \ge 1$ and $(V_{+f})_T \ge 1$ with probability 1 under ν_{-e} and apply this and the remaining calculations to $U_T - 1$, $(V_{+f})_T - 1$. In addition, we have

$$\mathbb{P}_{\nu_{-e}} [U_T \le 2]$$
, $\mathbb{P}_{\nu_{-e}} [(V_{+f})_T \le 2] \ge 0.499$ (Markov Inequality) $\mathbb{P}_{\nu_{-e}} [U_T \ge 2]$, $\mathbb{P}_{\nu_{-e}} [(V_{+f})_T \ge 2] \ge 0.39$ (Lemma 2.22)

It follows by Corollary 5.5 (with $\epsilon = 0.194$ and $p_m = 0.6$) that

$$\mathbb{P}_{\nu_{-e}}[U_T = 2|U_T + (V_{+f})_T = 4] \ge 0.13.$$

Therefore,

$$\mathbb{P}\left[\delta(u)_{T} = \delta(v)_{T} = 2\right] \ge \mathbb{P}\left[u, v, w \text{ trees, } \mathbf{e} \notin T\right] \mathbb{P}_{\nu_{-\mathbf{e}}}\left[U_{T} = (V_{+\mathbf{f}})_{T} = 2\right] \\ \ge (0.49)(0.029)(0.13) \ge 0.0018.$$

The lemma follows (i.e., *e* is 2-2 good) since $0.0018 \ge 3\epsilon_{1/2}$ for $\epsilon_{1/2} \le 0.0005$.

Otherwise, if $\mathbb{E}_{\nu}[V_T|\mathbf{e} \notin T] \leq \mathbb{E}_{\nu}[V_T] + 0.03$ then we will show that **f** is 2/2 good. We have,

$$\begin{split} \mathbb{E}_{\nu_{+f}}\left[(V_{+\mathbf{e}})_{T}\right], \mathbb{E}_{\nu_{+f}}\left[W_{T}\right] &\in [1-2\epsilon_{1/2}, 1.5+2\epsilon_{1/2}] \\ \mathbb{P}_{\nu_{+f}}\left[(V_{+\mathbf{e}})_{T} \leq 1\right], \mathbb{P}_{\nu_{+f}}\left[W_{T} \leq 1\right] &\geq 0.249 \\ \mathbb{P}_{\nu_{+f}}\left[(V_{+\mathbf{e}})_{T} \geq 1\right], \mathbb{P}_{\nu_{+f}}\left[W_{T} \geq 1\right] &\geq 0.63 \end{split} \tag{Lemma 2.21}$$

So, by Lemma 2.22 (with $\epsilon = 0.15$, $p_m = 0.7$), we get $\mathbb{P}_{\nu_{+f}}[W_T = 1 | (V_{+e})_T + W_T = 2] \ge 0.11$. On the other hand,

$$\mathbb{P}_{\nu_{+f}}\left[(V_{+\mathbf{e}})_T + W_T = 2\right] \ge \mathbb{P}_{\nu_{+f}}\left[\mathbf{e} \notin T\right] \mathbb{P}_{\nu_{+f-\mathbf{e}}}\left[(V_{+\mathbf{e}})_T + W_T = 2\right] \ge (0.49)(0.0582) \ge 0.0285$$

To derive the last inequality, we show $\mathbb{P}_{\nu_{+f-e}}[(V_{+e})_T + W_T = 2] \ge 0.0582$. This is because by negative association and Eq. (21)

$$\mathbb{E}_{\nu_{+f-e}}\left[(V_{+e})_{T} + W_{T}\right] = \mathbb{E}_{\nu_{+f-e}}\left[V_{T} + W_{T}\right] \\ \leq \mathbb{E}_{\nu_{-e}}\left[V_{T} + W_{T}\right] \leq \mathbb{E}_{\nu}\left[W_{T}\right] + 0.405 + \mathbb{E}_{\nu}\left[V_{T}\right] + 0.03 \leq 2.94;$$

So, since $(V_{+e})_T + W_T$ is always at least 1, so by Theorem 2.15, in the worst case, $\mathbb{P}_{\nu_{-e+f}}[(V_{+e})_T + W_T = 2]$ is the probability that the sum of two Bernoullis with success probability 1.94/2 is 1, which is 0.0582.

Therefore, similar to the previous case,

$$\mathbb{P}\left[\delta(u)_{T} = \delta(v)_{T} = 2\right] \ge \mathbb{P}\left[u, v, w \text{ trees, } f \in T\right] \mathbb{P}_{\nu_{+\mathbf{f}}}\left[(V_{+\mathbf{e}})_{T} = W_{T} = 2\right] \mathbb{P}_{\nu_{+\mathbf{f}}}\left[W_{T} = 1 | (V_{+\mathbf{e}})_{T} = W_{T} = 2\right]$$

$$\ge (0.49)(0.0285)(0.11) \ge 3\epsilon_{1/2}$$

for $\epsilon_{1/2} \leq 0.0005$ as desired.

5.4 2-1-1 Good Edges

Definition 5.18 (A, B, C-Degree Partitioning). For $u \in \mathcal{H}$, we define a partitioning of edges in $\delta(u)$: Let a, $b \subseteq u$ be minimal cuts in the hierarchy, i.e., a, $b \in \mathcal{H}$, such that $a \neq b$ and $x(\delta(a) \cap \delta(u))$, $x(\delta(b) \cap \delta(u)) \geq 1 - \epsilon_{1/1}$. Note that since the hierarchy is laminar, a, b cannot cross. Let $A = \delta(a) \cap \delta(u)$, $B = \delta(b) \cap \delta(u)$, $C = \delta(u) \setminus A \setminus B$.

If there is no cut $a \subseteq u$ (in the hierarchy) such that $x(\delta(a) \cap \delta(u)) \ge 1 - \epsilon_{1/1}$, we just let A, B be arbitrary set of edges in $\delta(u)$ which $x(A), x(B) \ge 1 - \epsilon_{1/1}$.

If there is just one minimal cut $a \subsetneq u$ (in the hierarchy) with $x(\delta(a) \cap \delta(u)) \geq 1 - \epsilon_{1/1}$, i.e., b does not exist in the above definition, then we define $A = \delta(a) \cap \delta(u)$. Let $a' \in \mathcal{H}$ be the unique child of u such that $a \subseteq a'$, i.e., a is equal to a' or a descendant of a'. Then we define $C = \delta(a') \cap \delta(u) \setminus \delta(a)$ and $B = (\delta(u) \setminus A) \setminus C$. Note that in this case since $x(\delta^{\uparrow}(a')) \leq 1 + \epsilon_{\eta}$, we have $x(B) \geq 1 - \epsilon_{\eta} \geq 1 - \epsilon_{1/1}$.

See Fig. 6 for an example. The following inequalities on *A*, *B*, *C* degree partitioning will be used in this section:

$$1 - \epsilon_{1/1} \le x(A), x(B) \le 1 + \epsilon_{\eta},$$

$$x(C) \le 2\epsilon_{1/1} + \epsilon_{\eta}.$$
 (22)

For an edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ and degree partitioning A, B, C of $\delta(u)$ we write $\mathbf{e}(A) = \mathbf{e} \cap A$. Note that $\mathbf{e}(A)$ is not really an edge bundle.

In this section we will define a constant p > 0 which is the minimum probability that an edge bundle is good.

Definition 5.19 (2-1-1 Happy/Good). Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a top edge bundle. Let $A, B, C \subseteq \delta(u)$ be a Degree Partitioning of edges $\delta(u)$ as defined in Definition 5.18. We say that \mathbf{e} is 2-1-1 happy with respect to u if the event

$$A_T = 1$$
, $B_T = 1$, $C_T = 0$, $\delta(v)_T = 2$, and u and v are both trees

occurs.

We say **e** is 2-1-1 good with respect to *u* if

$$\mathbb{P}\left[\mathbf{e} \text{ is 2-1-1 happy } wrt \ u\right] \geq p.$$

Definition 5.20 (2-2-2 Happy/Good). Let $\mathbf{e} = (\mathbf{u}, \mathbf{v}), \mathbf{f} = (\mathbf{v}, \mathbf{w})$ be top half-edge bundles (with $p(\mathbf{e}) = p(\mathbf{f})$). We say \mathbf{e}, \mathbf{f} are 2-2-2 happy (with respect to \mathbf{v}) if $\delta(\mathbf{u})_T = \delta(\mathbf{v})_T = \delta(\mathbf{w})_T = 2$ and $\mathbf{u}, \mathbf{v}, \mathbf{w}$ are all trees.

We say \mathbf{e} , \mathbf{f} are 2-2-2 good with respect to v if $\mathbb{P}\left[\mathbf{e}$, \mathbf{f} 2-2-2 happy $\right] \geq p$.

We will use the following notation: For a set of edges D, and an edge bundle \mathbf{e} , let $\mathbf{e}(D) := \mathbf{e} \cap D$.

The following theorem is the main result of this section.

Theorem 5.21. Let $v, S \in \mathcal{H}$ where p(v) = S, and let A, B, C be the degree partitioning of $\delta(v)$. For $p \geq 0.005\epsilon_{1/2}^2$, with $\epsilon_{1/2} \leq 0.0002$, $\epsilon_{1/1} \leq \epsilon_{1/2}/12$ and $\epsilon_{\eta} \leq \epsilon_{1/2}^2$, at least one of the following is true:

- i) $\delta^{\rightarrow}(v)$ has at least $1/2 \epsilon_{1/2}$ fraction of bad edges,
- ii) $\delta^{\rightarrow}(v)$ has at least $1/2 \epsilon_{1/2} \epsilon_{\eta}$ fraction of 2/1/1 good edges with respect to v.
- iii) There are two (top) half edge bundles $\mathbf{e}, \mathbf{f} \in \delta^{\rightarrow}(v)$ such that $x_{\mathbf{e}(B)} \leq \epsilon_{1/2}$, $x_{\mathbf{f}(A)} \leq \epsilon_{1/2}$, and \mathbf{e}, \mathbf{f} are 2/2/2 good (with respect to v).

We will prove this theorem after proving several intermediate lemmas (whose proofs can be found in Appendix A).

Lemma 5.22. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a top edge bundle such that $x_{\mathbf{e}} \le 1/2 - \epsilon_{1/2}$. If $12\epsilon_{1/1} \le \epsilon_{1/2} \le 0.001$ then, \mathbf{e} is 2/1/1 happy with probability at least $0.005\epsilon_{1/2}^2$.

Lemma 5.23. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a top edge bundle such that $x_{\mathbf{e}} \ge 1/2 + \epsilon_{1/2}$. If $12\epsilon_{1/1} \le \epsilon_{1/2} \le 0.001$, then, \mathbf{e} is 2/1/1 happy with respect to u with probability at least $0.006\epsilon_{1/2}^2$.

Lemma 5.24. For a good half top edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$, let A, B, C be the degree partitioning of $\delta(u)$, and let $V = \delta(v)_{-\mathbf{e}}$ (see Fig. 14). If $x_{\mathbf{e}(B)} \le \epsilon_{1/2}$ and $\mathbb{P}\left[(A_{-\mathbf{e}})_T + V_T \le 1\right] \ge 5\epsilon_{1/2}$ then \mathbf{e} is 2-1-1 good,

$$\mathbb{P}\left[\mathbf{e} \text{ 2-1-1 happy w.r.t. } u\right] \geq 0.005\epsilon_{1/2}^2$$

Lemma 5.25. Let $\mathbf{e} = (\mathbf{v}, \mathbf{u})$ and $\mathbf{f} = (\mathbf{v}, \mathbf{w})$ be good half top edge bundles and let A, B, C be the degree partitioning of $\delta(v)$ such that $x_{\mathbf{e}(B)}, x_{\mathbf{f}(B)} \leq \epsilon_{1/2}$. Then, one of \mathbf{e}, \mathbf{f} is 2-1-1 happy with probability at least $0.005\epsilon_{1/2}^2$.

Lemma 5.26. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a good half edge bundle and let A, B, C be the degree partitioning of $\delta(u)$ (see Fig. 15). If $12\epsilon_{1/1} \le \epsilon_{1/2} \le 0.001$ and $x_{\mathbf{e}(A)}, x_{\mathbf{e}(B)} \ge \epsilon_{1/2}$, then

$$\mathbb{P}\left[\mathbf{e} \text{ 2-1-1 happy w.r.t } u\right] \geq 0.02\epsilon_{1/2}^2$$
.

Lemma 5.27. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$, $\mathbf{f} = (\mathbf{v}, \mathbf{w})$ be two good top half edge bundles and let A, B, C be degree partitioning of $\delta(v)$ such that $x_{\mathbf{e}(B)}, x_{\mathbf{f}(A)} \leq \epsilon_{1/2}$. If \mathbf{e} , \mathbf{f} are not 2-1-1 good with respect to v, and $12\epsilon_{1/1} \leq \epsilon_{1/2} \leq 0.0002$, then \mathbf{e} , \mathbf{f} are 2-2-2 happy with probability at least 0.01.

Proof of Theorem 5.21. Suppose case (i) does not happen. Since every bad edge has fraction at least $1/2 - \epsilon_{1/2}$ this means that $\delta(v)$ has no bad edges. First, notice by Lemma 5.22 and Lemma 5.23 any non half-edge in $\delta^{\rightarrow}(v)$ is 2/1/1 good (with respect to v). If there is only one half edge in $\delta^{\rightarrow}(v)$, then we have at least fraction $1 - \epsilon_{\eta} - (1/2 + \epsilon_{1/2})$ fraction of 2-1-1 good edges and we are done with case (ii). Otherwise, there are two good half edges $\mathbf{e}, \mathbf{f} \in \delta^{\rightarrow}(v)$.

First, by Lemma 5.26 if $x_{\mathbf{e}(A)}, x_{\mathbf{e}(B)} \ge \epsilon_{1/2}$, then **e** is 2/1/1 good (w.r.t., v) and we are done. Similarly, if $x_{\mathbf{f}(A)}, x_{\mathbf{f}(B)} \ge \epsilon_{1/2}$, then **f** is good. So assume none of these happens.

Furthermore by Lemma 5.25 if $x_{\mathbf{e}(B)}$, $x_{\mathbf{f}(B)} \le \epsilon_{1/2}$ (or $x_{\mathbf{e}(A)}$, $x_{\mathbf{f}(A)} \le \epsilon_{1/2}$) then one of \mathbf{e} , \mathbf{f} is 2/1/1 good.

So, the only remaining case is when **e**, **f** are not 2-1-1 good and $x_{\mathbf{e}(B)}$, $x_{\mathbf{f}(A)} \le \epsilon_{1/2}$. But in this case by Lemma 5.27, **e**, **f** are 2/2/2 good; so (iii) holds.

Lemma 5.28. For a degree cut $S \in \mathcal{H}$, and $u \in \mathcal{A}(S)$, let A, B, C be the degree partition of u. Then, $A \cap \delta^{\rightarrow}(u)$ has fraction at most $1/2 + 4\epsilon_{1/2}$ of good edges that are not 2-1-1 good (w.r.t., u).

Proof. Suppose by way of contradiction that there is a set $D \subseteq A^{\rightarrow}$ of good edges that are not 2-1-1 good w.r.t. u with $x(D) \ge \frac{1}{2} + 4\epsilon_{1/2}$. By Lemma 5.22 and Lemma 5.23, every edge in D is part of a half edge bundle.

There are at least two half edge bundles **e**, **f** such that $x(D \cap \mathbf{e})$, $x(D \cap \mathbf{f}) \ge \epsilon_{1/2}$, as there are at most four half edge bundles in $\delta^{\rightarrow}(u)$ (and using that for any half edge bundle **e**, $x_{\mathbf{e}} \le \frac{1}{2} + \epsilon_{1/2}$). Since $D \subseteq A^{\rightarrow}$, we have

$$x(A \cap \mathbf{e}), x(A \cap \mathbf{f}) \ge \epsilon_{1/2}.$$

Since $x(A \cap \mathbf{e}) \ge \epsilon_{1/2}$, if $x(B \cap \mathbf{e}) \ge \epsilon_{1/2}$ then, by Lemma 5.26 \mathbf{e} is 2-1-1 good. But since every edge in D is not 2-1-1 good w.r.t u, we must have $x(B \cap \mathbf{e}) < \epsilon_{1/2}$. The same also holds for \mathbf{f} . Finally, since $x(B \cap \mathbf{e}) < \epsilon_{1/2}$ and $x(B \cap \mathbf{f}) < \epsilon_{1/2}$ by Lemma 5.25 at least one of \mathbf{e} , \mathbf{f} is 2-1-1 good w.r.t u. This is a contradiction.

6 Matching

Definition 6.1 (ϵ_F fractional edge). For $z \geq 0$ we say that z is ϵ_F -fractional if $\epsilon_F \leq z \leq 1 - \epsilon_F$.

The following lemma is the main result of this section.

Lemma 6.2 (Matching Lemma). For a degree cut $S \in \mathcal{H}$, let $F(S) \subseteq \mathcal{A}(S)$ denote the set of atoms u such that $x(\delta^{\uparrow}(u))$ is ϵ_F -fractional. Then for any $\epsilon_F \leq 1/10$, $\epsilon_B \geq 21\epsilon_{1/2}$, $\alpha \geq 2\epsilon_{\eta}$, there is a matching from good edges (see Definition 5.13) in $E^{\to}(S)$ to edges in $\delta(S)$ such that every good edge bundle e = (u, v) (where $u, v \in \mathcal{A}(S)$) is matched to a fraction $m_{\mathbf{e},v}$ of edges in $\delta^{\uparrow}(u)$ and a fraction $m_{\mathbf{e},v}$ of $\delta^{\uparrow}(v)$ where

$$m_{\mathbf{e},u}F_u + m_{\mathbf{e},v}F_v \le x_e(1+\alpha),\tag{23}$$

 $m_{\mathbf{e},u} = m_{\mathbf{e},v} = 0$ if e is bad, and for every atom $u \in \mathcal{A}(S)$, where for an atom $u \in \mathcal{A}(S)$,

$$F_u = 1 - \epsilon_B \mathbb{I}\left\{x(\delta^{\uparrow}(u)) \text{ is } \epsilon_F \text{ fractional}
ight\}$$
 ,

i.e., it is active if u is ϵ_F -fractional, and

$$\sum_{e \in \delta^{\to}(u)} m_{\mathbf{e},u} = x(\delta^{\uparrow}(u)) Z_u \tag{24}$$

where for $u \in A(S)$,

$$Z_u := \left(1 + \mathbb{I}\left\{|\mathcal{A}(S)| \ge 4, x(\delta^{\uparrow}(u)) \le \epsilon_F\right\}\right)$$

which is active when $\delta^{\uparrow}(u)$ is very close to zero.

Roughly speaking, the intention of the above lemma is to match edges in $E^{\rightarrow}(S)$ to a similar fraction of edges from endpoints that go higher. Eq. (23) says that if $x(\delta^{\uparrow}(u))$ is fractional then edges incident to u can be matched to a larger faction of edges in $\delta^{\uparrow}(u)$. On the other hand, Eq. (24) says that if $x(\delta^{\uparrow}(u)) \approx 0$, then a larger fraction of edges will match to edges in $\delta^{\uparrow}(u)$. This is the matching that we use in order to decide which edges we will have positive slack to compensate for the negative slack of edges going higher.

Throughout this section we adopt the following notation: For a cut $S \in \mathcal{H}$ and a set $W \subseteq \mathcal{A}(S)$, we write

$$E(W, S \setminus W) := \bigcup_{a \in W, b \in \mathcal{A}(S) \setminus W} E(a, b),$$

$$\delta^{\uparrow}(W) := \bigcup_{a \in W} \delta^{\uparrow}(a) = \delta(W) \cap \delta(S),$$

$$\delta^{\rightarrow}(W) := \bigcup_{a \in W} \delta^{\rightarrow}(a).$$

Note that in $\delta^{\rightarrow}(W) \not\subseteq \delta(W)$ since it includes edge bundles between atoms in W. Before proving the main lemma we record the following facts.

Lemma 6.3. For any $S \in \mathcal{H}$ and $W \subseteq \mathcal{A}(S)$, we have

$$x(\delta^{\to}(W)) \ge \frac{1}{2} \sum_{a \in W} x(\delta(a)) - \epsilon/2 \ge |W| - \epsilon/2$$

where the sum is over the vertices in W.

Proof. We have

$$x(\delta^{\rightarrow}(W)) = \frac{1}{2} \left(\sum_{a \in W} (x(\delta(a)) + x(E(W, S \setminus W)) - x(\delta^{\uparrow}(W)) \right).$$

Since $x(\delta(S \setminus W)) \ge 2$ and $x(\delta(S)) \le 2 + \epsilon$, we have:

(a)
$$x(E(W, S \setminus W)) + x(\delta^{\uparrow}(S \setminus W))) \ge 2$$
 and (b) $x(\delta^{\uparrow}(W)) + x(\delta^{\uparrow}(S \setminus W)) \le 2 + \epsilon$.

Subtracting (b) from (a), we get

$$x(E(W,S \setminus W)) - x(\delta^{\uparrow}(W)) \ge -\epsilon,$$

which after substituting into the above equation, completes the proof of the first inequality in the lemma statement. The second inequality follows from the fact that $\delta(a) \ge 2$ for each atom a.

Lemma 6.4. For $S \in \mathcal{H}$, if $|\mathcal{A}(S)| = 3$ then there are no bad edges in $E^{\rightarrow}(S)$.

Proof. Suppose $A(S) = \{u, v, w\}$ and $\mathbf{e} = (u, v)$ is a bad edge bundle. Then $|x_{\mathbf{e}} - \frac{1}{2}| \le \epsilon_{1/2}$. In addition, by Theorem 5.14, $x(\delta^{\uparrow}(u)), x(\delta^{\uparrow}(v)) \le 1/2 + 9\epsilon_{1/2}$. Therefore,

$$x_{(\mathbf{u},\mathbf{w})} = x(\delta(u)) - x_{\mathbf{e}} - x(\delta^{\uparrow}(u)) \ge 1 - 10\epsilon_{1/2}.$$

Similarly, $x_{(\mathbf{v},\mathbf{w})} \geq 1 - 10\epsilon_{1/2}$. Finally, since $x(\delta(S)) \geq 2$, and $x(\delta^{\uparrow}(u))$, $x(\delta^{\uparrow}(v)) \leq 1/2 + 9\epsilon_{1/2}$, we must have $x(\delta^{\uparrow}(w)) \geq 1 - 18\epsilon_{1/2}$. But, this contradicts the assumption that $w \in \mathcal{H}$ must satisfy $x(\delta(w)) \leq 2 + \epsilon_{\eta}$.

Proof of Lemma 6.2. We will prove this by setting up a max-flow min-cut problem. Construct a graph with vertex set $\{s, X, Y, t\}$, where s, t are the source and sink. We identify X with the set of good edge bundles in $E^{\rightarrow}(S)$ and Y with the set of atoms in $\mathcal{A}(S)$. For every edge bundle $\mathbf{e} \in X$, add an arc from s to \mathbf{e} of capacity $c(s, \mathbf{e}) := (1 + \alpha)x_{\mathbf{e}}$. For every $u \in \mathcal{A}(S)$, there is an arc (u, t) with capacity

$$c(u,t) = x(\delta^{\uparrow}(u))F_uZ_u.$$

Finally, connect $\mathbf{e} = (u, v) \in X$ to nodes u and $v \in Y$ with a directed edge of infinite capacity, i.e., $c(\mathbf{e}, u) = c(\mathbf{e}, v) = \infty$. We will show below that there is a flow saturating t, i.e. there is a flow of value

$$c(t) := \sum_{u \in \mathcal{A}(S)} c(u, t) = \sum_{u \in \mathcal{A}(S)} x(\delta^{\uparrow}(u)) F_u Z_u.$$

Suppose that in the corresponding max-flow, there is a flow of value $f_{e,u}$ on the edge (e, u). Define

$$m_{\mathbf{e},u} := \frac{f_{\mathbf{e},u}}{F_{u}}.$$

Then (23) follows from the fact that the flow leaving \mathbf{e} is at most the capacity of the edge from s to \mathbf{e} , and (24) follows by conservation of flow on the node u (after cancelling out F_u from both sides).

We have left to show that for any s-t cut A, \overline{A} where $s \in A$, $t \in \overline{A}$ that the capacity of this cut is at least c(t).

Claim 6.5. If $A = \{s\}$, then capacity of (A, \overline{A}) is at least c(t).

Proof. If |A(S)| = 3 then $Z_u = 1$ for all $u \in A(S)$ and by Lemma 6.4 all edges are good. Also,

$$x(E^{\to}(S)) = \frac{1}{2} \sum_{a \in \mathcal{A}(S)} (x(\delta(a)) - x(\delta^{\uparrow}(a))) \ge \frac{2|\mathcal{A}(S)| - (2 + \epsilon_{\eta})}{2} = 2 - \epsilon_{\eta}/2.$$

So, $x(E^{\rightarrow}(S)) \ge 2 - \epsilon_{\eta}/2$. Thus, for $\alpha \ge 2\epsilon_{\eta}$ we have

$$c(s)(1+\alpha) \ge (2-\epsilon_{\eta}/2)(1+\alpha) \ge 2+\epsilon_{\eta} \ge x(\delta(S)) = c(t)$$

as desired.

Now, suppose $|\mathcal{A}(S)| \geq 4$. By Theorem 5.14 there is at most one bad half edge adjacent to every vertex. Therefore there are at most $|\mathcal{A}(S)|/2$ bad edges in total (the bound is met if they form a perfect matching) which contributes to at most a total of $(1/2 + \epsilon_{1/2})|\mathcal{A}(S)|/2 =: x_B$

fraction. So, there is a fraction of at least $x_G := x(E^{\to}(S)) - x_B \ge |\mathcal{A}(S)| - 1 - \epsilon_{\eta}/2 - x_B$ of good edges. So,

$$(1+\alpha)x_{G} \geq (1+\alpha)\left(|\mathcal{A}(S)|(\frac{3}{4} - \frac{\epsilon_{1/2}}{2}) - 1 - \frac{\epsilon_{\eta}}{2}\right)$$

$$\geq (1+\alpha)\left(|\mathcal{A}(S)|(\frac{3}{4} - \frac{\epsilon_{1/2}}{2} - \epsilon_{F}) - 1 - \frac{\epsilon_{\eta}}{2} + \epsilon_{F}|\mathcal{A}(S)|.\right)$$

$$\geq 2 + \epsilon_{\eta} + \epsilon_{F}|\mathcal{A}(S)| \geq c(t).$$

where the final inequality holds, e.g., for $\alpha \ge 2\epsilon_{\eta}$ and since $|\mathcal{A}(S)| \ge 5$ and $\epsilon_F \le 1/10$.

If $|\mathcal{A}(S)| = 4$, and we have 0 or 1 bad edges, then $x_G \geq 2.5 - \epsilon_{\eta}/2 - \epsilon_{1/2}$, so $(1 + \alpha)x_G \geq (1 + 2\epsilon_{\eta})(2.5 - \epsilon_{\eta}/2 - \epsilon_{1/2}) \geq 2 + \epsilon_{\eta} + 2\epsilon_F$ for $\epsilon_F < \frac{1}{10}$ (and noting that with $|\mathcal{A}(S)| = 4$ at most 2 nodes can have $\delta^{\uparrow}(u) \leq \epsilon_F$).

Finally, suppose that $|\mathcal{A}(S)| = 4$ and there are two bad edges. Then they form a perfect matching inside S and for each $u \in \mathcal{A}(S)$, $x(\delta^{\uparrow}(u)) \leq 1/2 + 9\epsilon_{1/2}$ (see Theorem 5.14).

It also must be the case that $x(\delta^{\uparrow}(u)) \geq \epsilon_F$ for each $u \in \mathcal{A}(S)$. If not, there would have to be a node $u' \in \mathcal{A}(S)$ such that $x(\delta^{\uparrow}(u')) \geq (2 - \epsilon_F)/3 > 1/2 + 9\epsilon_{1/2}$, which is a contradiction to u' having an incident bad edge. Thus, for each $u \in \mathcal{A}(S)$, $x(\delta^{\uparrow}(u))$ is ϵ_F -fractional, i.e., $F_u = 1 - \epsilon_B$ and $Z_u = 1$ implying that $c(t) \leq (2 + \epsilon_\eta)(1 - \epsilon_B)$. Therefore, we have

$$c(s) = (1+\alpha)x_G \ge (1+\alpha)(3-\epsilon_{\eta}/2-2(1/2+\epsilon_{1/2})) = (1+\alpha)(2-2\epsilon_{1/2}-\epsilon_{\eta}/2)$$

and the rightmost quantity is at least c(t) for $\epsilon_B \geq 2\epsilon_{1/2}$ and $\alpha \geq 2\epsilon_n$.

From now on, we assume that the min s-t cut $A \neq \{s\}$. In the following we will prove that for any set of *atoms* $W \subseteq S$, we have:

$$c(s, \delta^{\rightarrow}(W)) = (1 + \alpha)x_G(\delta^{\rightarrow}(W)) \ge c(\delta^{\uparrow}(W), t)$$
(25)

where for a set F of edges we write $x_G(F)$ to denote the total fractional value of good edges in F. Let $A_X = A \cap X$, $A_Y = A \cap Y$ and so on. Assuming the above inequality, let us prove the lemma: First, for the set of edges A_X chosen from X, let Q be the set of endpoints of all edge bundles in A_X (in A(S)).

Observe that we must choose all atoms in Q inside A_Y due to the infinite capacity arcs, i.e., $Q \subseteq A_Y$. Let $W = S \setminus Q$. Note that $W \neq S$. Then:

$$\begin{split} \operatorname{cap}(A,\overline{A}) &= c(A_Y,t) + c(s,\overline{A}_X) \\ &\geq c(\delta^{\uparrow}(Q),t) + c(s,\delta^{\rightarrow}(W)) \\ &= c(\delta^{\uparrow}(S),t) - c(\delta^{\uparrow}(W)) + c(s,\delta^{\rightarrow}(W)) \geq c(\delta^{\uparrow}(S),t), \end{split}$$

where the last inequality follows by (25).

Finally, we prove (25). Suppose atoms in W are adjacent to k bad edges. Then

$$x_G(\delta^{\rightarrow}(W)) = x(\delta^{\rightarrow}(W)) - x_B(\delta^{\rightarrow}(W))$$

which by Lemma 6.3 and the fact that each bad edge has fraction at most $1/2 + \epsilon_{1/2}$, is

$$\geq |W| - \epsilon_{\eta}/2 - k(1/2 + \epsilon_{1/2}).$$
 (26)

To upper bound $c(\delta^{\uparrow}(W), t)$, we observe that for any $u \in \mathcal{A}(S)$,

$$c(u,t) \leq \begin{cases} x(\delta^{\uparrow}(u))Z_u \leq 1/5 & \text{if } x(\delta^{\uparrow}(u)) < \epsilon_F \\ (1/2 + 9\epsilon_{1/2})(1 - \epsilon_B) & \text{if } x(\delta^{\uparrow}(u)) > \epsilon_F \text{ and } u \text{ incident to bad edge} \\ 1 + \epsilon_{\eta} & \text{otherwise, using Lemma 2.7.} \end{cases}$$

Therefore, we can write,

$$c(\delta^{\uparrow}(W),t) \leq k(1/2 + 9\epsilon_{1/2})(1 - \epsilon_B) + (|W| - k)(1 + \epsilon_{\eta}).$$

Now, to prove (25), using (26), it is enough to choose α and ϵ_B such that,

$$(1+\alpha)\left(|W| - \epsilon_{\eta}/2 - k(1/2 + \epsilon_{1/2})\right) \ge k(1/2 + 9\epsilon_{1/2})(1 - \epsilon_B) + (|W| - k)(1 + \epsilon_{\eta}),$$

or equivalently,

$$|W|(\alpha - \epsilon_{\eta}) \ge k(\alpha/2 + 10\epsilon_{1/2} + \alpha\epsilon_{1/2} - \epsilon_{B}/2 - 9\epsilon_{B}\epsilon_{1/2} - \epsilon_{\eta}) + \frac{\epsilon_{\eta}}{2}(1 + \alpha)$$

Since every atom is adjacent to at most one bad edge, $k \le |W|$ and $|W| \ge 1$, the inequality follows using $\epsilon_B \geq 21\epsilon_{1/2}$ and $\alpha > 2\epsilon_{\eta}$ and $\epsilon_{1/2} \leq 0.0005$ and $\epsilon_{\eta} \leq \epsilon_{1/2}^2$.

Reduction and payment

In this section we prove Theorem 4.33.

In Section 5 we defined a number of happy events, such as 2-1-1 happy or 2-2-2 happy and showed that each of these events occurs with probability at least p. In this section, we will subsample these events to define a corresponding decrease event that occurs with probability exactly 12 p.

Reduction Events.

- i) For each polygon cut $S \in \mathcal{H}$, let \mathcal{R}_S be the indicator of a uniformly random subset of measure p of the max flow event \mathcal{E}_S . Note that when $\mathcal{R}_S = 1$ then in particular we know that the polygon *S* is happy.
- ii) For a top edge bundle $\mathbf{e} = (u, v)$ define

or a top edge bundle
$$\mathbf{e} = (u, v)$$
 define
$$\mathcal{H}_{\mathbf{e}, u} = \begin{cases} 1 & \text{if } \mathbf{e} \text{ is } 2\text{-}1\text{-}1 \text{ happy and good w.r.t. } u \\ 1 & \text{if } \mathbf{e} \text{ is } 2\text{-}2\text{-}2 \text{ happy and good w.r.t. } u, \text{ but not } 2\text{-}1\text{-}1 \text{ good with respect to } u \\ 1 & \text{if } \mathbf{e} \text{ is } 2\text{-}2 \text{ happy and good, but not } 2\text{-}1\text{-}1 \text{ or } 2\text{-}2\text{-}2 \text{ good with respect to } u \\ 0 & \text{otherwise.} \end{cases}$$

¹²Suppose that under the distribution μ on spanning trees, some event \mathcal{D}' has probability $q \geq p$ and we seek to define an event $\mathcal{D} \subseteq \mathcal{D}'$ that has probability *exactly p*. To this end, one can copy every tree T in the support of μ , exactly $\lfloor \frac{kq}{p} \rfloor$ times for some integer k > 0 and whenever we sample T we choose a copy uniformly at random. So, to get a probability exactly p for an event, we say this event occurs if for a "feasible" tree T one of the first k copies are sampled. Now, as $k \to \infty$ the probability that \mathcal{D} occurs converges to p. Now, for a number of decreasing events, $\mathcal{D}_1, \mathcal{D}_2, \ldots$, that occur with probabilities q_1, q_2, \ldots (respectively), we just need to let k be the least common multiple of $p/q_1, p/q_2, \ldots$ and follow the above procedure. Another method is to choose an independent Bernoulli with success probability p/q for any such event \mathcal{D} .

and let $\mathcal{H}_{\mathbf{e},v}$ be defined similarly. Since p is a lower bound on the probability an edge is good, we may now let $\mathcal{R}_{\mathbf{e},u}$ and $\mathcal{R}_{\mathbf{e},v}$ be indicators of subsets of measure p of $\mathcal{H}_{\mathbf{e},u}$ and $\mathcal{H}_{\mathbf{e},v}$ respectively (note $\mathcal{R}_{\mathbf{e},u}$ and $\mathcal{R}_{\mathbf{e},v}$ may overlap). In this way every top edge bundle $\mathbf{e} = (u,v)$ is associated with indicators $\mathcal{R}_{\mathbf{e},u}$ and $\mathcal{R}_{\mathbf{e},v}$.

We set $\beta = \eta/8$ and $\tau = 0.571\beta$. Define $r : E \to \mathbb{R}_{\geq 0}$ as follows: For any (non-bundle) edge e,

$$r_e = \begin{cases} \beta x_e \mathcal{R}_S & \text{if } \mathsf{p}(e) = S \text{ for a polygon cut } S \in \mathcal{H} \\ \frac{1}{2} \tau x_e (\mathcal{R}_{\mathbf{f},u} + \mathcal{R}_{\mathbf{f},v}) & \text{if } e \in \mathbf{f} \text{ for a top edge bundle } \mathbf{f} = (u,v) \end{cases}$$

Increase Events Let **E** be the set of edge bundles, i.e., top/bottom edge bundles. Now, we define the increase vector $I : \mathbf{E} \to \mathbb{R}_{>0}$ as follows:

• **Top edges.** Let $m_{\mathbf{e},u}$ be defined as in Lemma 6.2. For each top edge bundle $\mathbf{e} = (u,v)$, let

$$I_{\mathbf{e},u} := \sum_{g \in \delta^{\uparrow}(u)} r_g \cdot \frac{m_{\mathbf{e},u}}{\sum_{\mathbf{f} \in \delta^{\to}(u)} m_{\mathbf{f},u}} \mathbb{I} \left\{ u \text{ is odd} \right\}, \tag{27}$$

and define $I_{e,v}$ analogously. Let $I_e = I_{e,u} + I_{e,v}$.

• **Bottom edges.** For each bottom edge bundle *S* with polygon partition *A*, *B*, *C*, let $r(A) := \sum_{f \in A} r_f$, $r(B) := \sum_{f \in B} r_f$, and $r(C) := \sum_{f \in C} r_f$. Then set

$$I_{S} := (1 + \epsilon_{\eta}) \Big(\max\{r(A) \cdot \mathbb{I} \{S \text{ not left happy}\}, r(B) \cdot \mathbb{I} \{S \text{ not right happy}\} \Big)$$
$$+ r(C) \mathbb{I} \{S \text{ not happy}\} \Big). \tag{28}$$

The following theorem is the main technical result of this section.

Theorem 7.1. For any good top edge bundle \mathbf{e} , $\mathbb{E}\left[I_{\mathbf{e}}\right] \leq (1 - \frac{\epsilon_{1/1}}{6})p\tau x_{\mathbf{e}}$, and for any bottom edge bundle S, $\mathbb{E}\left[I_{S}\right] \leq 0.99994\beta p$.

Using this theorem, we can prove the desired theorem:

Theorem 4.33 (Main Payment Theorem). For an LP solution x^0 and x be x^0 restricted to E and a hierarchy \mathcal{H} for some $\epsilon_{\eta} \leq 10^{-10}$, the maximum entropy distribution μ with marginals x satisfies the following:

- i) There is a set of good edges $E_g \subseteq E \setminus \delta(\{u_0, v_0\})$ such that any bottom edge e is in E_g and for any (non-root) $S \in \mathcal{H}$ such that p(S) is a degree cut, we have $x(E_g \cap \delta(S)) \ge 3/4$.
- ii) There is a random vector $s: E_g \to \mathbb{R}$ (as a function of $T \sim \mu$) such that for all $e, s_e \geq -x_e \eta/8$ (with probability 1), and
- iii) If a polygon cut u with polygon partition A, B, C is not left happy, then for any set $F \subseteq E$ with p(e) = u for all $e \in F$ and $x(F) \ge 1 \epsilon_{\eta}/2$, we have

$$s(A) + s(F) + s^{-}(C) \ge 0$$

where $s^-(C) = \sum_{e \in C} \min\{s_e, 0\}$. A similar inequality holds if u is not right happy.

- iv) For every cut $S \in \mathcal{H}$ such that p(S) is not a polygon cut, if $\delta(S)_T$ is odd, then $s(\delta(S)) \geq 0$.
- v) For a good edge $e \in E_g$, $\mathbb{E}[s_e] \le -\epsilon_P \eta x_e$ (see Eq. (31) for definition of ϵ_P).

Proof of Theorem 4.33. First, we set the constants:

$$\epsilon_{1/2} = 0.0002, \epsilon_{1/1} = \frac{\epsilon_{1/2}}{12}, p = 0.005\epsilon_{1/2}^2, \epsilon_M = 0.00025, \tau = 0.571\beta, \beta = \eta/8.$$
 (29)

Define E_g to be the set of bottom edges together with any edge e which is part of a good top edge bundle. Now, we verify (i): We show for any $S \in \mathcal{H}$ such that p(S) is a degree cut, $x(E_g \cap \delta(S)) \geq 3/4$. First, by Theorem 5.14, if $x(\delta^{\uparrow}(S)) \geq 1/2 + 9\epsilon_{1/2}$ then all edges in $\delta^{\rightarrow}(S)$ are good, so the claim follows because by Lemma 2.7, $x(\delta^{\rightarrow}(S)) \geq 1 - \epsilon_{\eta} \geq 3/4$. Otherwise, $x(\delta^{\uparrow}(S)) \leq 1/2 + 9\epsilon_{1/2}$. Then, by Theorem 5.14 there is at most one bad edge in $\delta^{\rightarrow}(S)$. Therefore, there is a fraction at least $x(\delta^{\rightarrow}(S)) - (1/2 + \epsilon_{1/2}) \geq 3/4$ of good edges in $\delta^{\rightarrow}(S)$.

For any edge $e \in E'$ define

$$s_e = -r_e + \begin{cases} I_{\mathbf{f}} \frac{x_e}{x_{\mathbf{f}}} & \text{if } e \in \mathbf{f} \text{ for a top edge bundle } \mathbf{f}, \\ I_S x_e & \text{if } p(e) = S \text{ for a polygon cut } S \in \mathcal{H}. \end{cases}$$
(30)

Now, we verify (ii): First, we observe that $s_e = 0$ (with probability 1) if e is part of a bad edge bundle since we defined decrease events only for good edges and $m_{e,u}$ is non-zero only for good edge bundles. Since $r_e \le \beta x_e$ for bottom edges and $r_e \le \tau x_e$ for top edges, and $\tau \le \beta \le \eta/8$, we have that $r_e \le x_e \eta/8$. It follows that $s_e \ge -x_e \eta/8$.

Now, we verify (iii): Suppose a polygon cut u is not left-happy. Since u is not happy we must have $\mathcal{R}_u = 0$ and $r_e = 0$ for any $e \in F$. Therefore,

$$s(A) + s(F) + s^{-}(C) = s(A) + I_{S}x(F) + s^{-}(C)$$

$$\geq -r(A) + (1 + \epsilon_{\eta})(r_{A} + r_{C})(1 - \epsilon_{\eta}/2) - r(C) \geq 0.$$

where we used that $x(F) \ge 1 - \epsilon_{\eta}/2$.

Now, we verify (iv): Let $S \in \mathcal{H}$, where p(S) is a degree cut. If S is odd, then $r_e = 0$ for all edges $e \in \delta^{\rightarrow}(S)$; so by Eq. (27)

$$\begin{split} s(\delta(S)) &\geq -\sum_{g \in \delta^{\uparrow}(S)} r_g + \sum_{\mathbf{e} \in \delta^{\rightarrow}(S)} I_{\mathbf{e},S} \\ &= -\sum_{g \in \delta^{\uparrow}(S)} r_g + \sum_{\mathbf{e} \in \delta^{\rightarrow}(S)} \sum_{g \in \delta^{\uparrow}(S)} r_g \frac{m_{\mathbf{e},S}}{\sum_{\mathbf{f} \in \delta^{\rightarrow}(S)} m_{\mathbf{f},S}} = 0. \end{split}$$

Finally, we verify (v): Here, we use Theorem 7.1. For a good top edge *e* that is part of a top edge bundle **f** we have

$$\mathbb{E}\left[s_{e}\right] = -\mathbb{E}\left[r_{e}\right] + \mathbb{E}\left[I_{f}\right] \frac{x_{e}}{x_{f}} \leq -\tau p x_{e} + \left(1 - \frac{\epsilon_{1/1}}{6}\right) p \tau x_{e} = -\frac{\epsilon_{1/1}}{6} p \tau x_{e}.$$

On the other hand, for a bottom edge e with p(e) = S, then

$$\mathbb{E}\left[s_e\right] = -\mathbb{E}\left[r_e\right] + \mathbb{E}\left[I_S\right]x_e \le -\beta p x_e + 0.99994p\beta x_e \le -0.00006p\beta x_e.$$

Finally, we can let

$$\epsilon_P := \frac{\epsilon_{1/1}}{6} p(\tau/\eta) = \frac{\epsilon_{1/2}}{72} 0.005 \epsilon_{1/2}^2 \frac{0.571}{8} \ge 0.0000049 \epsilon_{1/2}^3 \ge 3.9 \cdot 10^{-17}$$
(31)

as desired. \Box

In the rest of this section we prove Theorem 7.1. Throughout the proof, we will repeatedly use the following facts proved in Section 5: If a top edge e = (u, v) that is part of a bundle f is reduced (equivalently $\mathcal{H}_{f,u} = 1$ or $\mathcal{H}_{f,v} = 1$), then u and v are trees, which means that tree sampling inside u and v is independent of the reduction of e.

Note however, that conditioning on a near-min-cut or atom to be a tree increases marginals inside and reduces marginals outside as specified by Lemma 2.23. Since for any $S \in \mathcal{H}$, $x(\delta(S)) \le 2 + \epsilon_{\eta}$, the overall change is $\pm \epsilon_{\eta}/2$.

The proof of Theorem 7.1 simply follows from Lemma 7.2 and Lemma 7.7 that we will prove in the following two sections.

7.1 Increase for Good Top Edges

The following lemma is the main result of this subsection.

Lemma 7.2 (Top Edge Increase). Let $S \in \mathcal{H}$ be a degree cut and $\mathbf{e} = (u, v)$ a good edge bundle with $p(\mathbf{e}) = S$. If $\epsilon_{1/2} \leq 0.0002$, $\epsilon_{1/1} \leq \epsilon_{1/2}/12$ and $\epsilon_{\eta} \leq \epsilon_{1/2}^2$, $\epsilon_F = 1/10$ then

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] + \mathbb{E}\left[I_{\mathbf{e},v}\right] \leq p\tau x_{\mathbf{e}} \left(1 - \frac{\epsilon_{1/1}}{6}\right).$$

We will use the following technical lemma to prove the above lemma.

Lemma 7.3. Let $S \in \mathcal{H}$ be a degree cut with an atom $u \in \mathcal{A}(S)$. If $x(\delta^{\uparrow}(u)) > \epsilon_F$, $\epsilon_{1/2} \leq 0.0002$, $\epsilon_{1/1} \leq \epsilon_{1/2}/12$, and $\epsilon_F = 1/10$ then we have

$$\sum_{\substack{g \in \delta^{\uparrow}(u), \\ g \in \mathbf{f} = (u',v') \text{ good top}}} \frac{1}{2} \tau x_g \cdot (\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},u'}\right] + \mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},v'}\right])$$
(32)

$$+\sum_{g\in\delta^{\uparrow}(u),\mathsf{p}(g)=S}\beta x_g\cdot\mathbb{P}\left[\delta(u)_T \ odd|\mathcal{R}_S\right]\leq \tau(1-\frac{\epsilon_{1/1}}{5})x(\delta^{\uparrow}(u))F_u,$$

where recall we set $F_u := 1 - \epsilon_B \mathbb{I} \{ u \in F(S) \}$ in Lemma 6.2, where we take $\epsilon_B := 21\epsilon_{1/2}$.

Proof of Lemma 7.2. By linearity of expectation and using Eq. (27):

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] = \frac{m_{\mathbf{e},u}}{\sum_{\mathbf{f}\in\delta^{\to}(u)} m_{\mathbf{f},u}} \mathbb{E}\left[\sum_{g\in\delta^{\uparrow}(u)} r_g \cdot \mathbb{I}\left\{u \text{ is odd}\right\}\right]$$

$$= \frac{m_{\mathbf{e},u}}{\sum_{\mathbf{f}\in\delta^{\to}(u)} m_{\mathbf{f},u}} \left(\sum_{\substack{g\in\delta^{\uparrow}(u):\\g\in\mathbf{f}=(u',v')\text{ good top}}} \frac{1}{2} \tau x_g \left(\mathbb{P}\left[\mathcal{R}_{\mathbf{f},u'},\delta(u)_T \text{ odd}\right] + \mathbb{P}\left[\mathcal{R}_{\mathbf{f},v'},\delta(u)_T \text{ odd}\right]\right)$$

$$+ \sum_{g\in\delta^{\uparrow}(u):p(g)=Spolygon} \beta x_g \mathbb{P}\left[\mathcal{R}_S,\delta(u)_T \text{ odd}\right]\right)$$
(33)

A similar equation holds for $\mathbb{E}[I_{e,v}]$.

The case where $x(\delta^{\uparrow}(u)) \leq \epsilon_F$ or $x(\delta^{\uparrow}(v)) \leq \epsilon_F$ is dealt with in Lemma 7.6. So, consider the case where $x(\delta^{\uparrow}(u)), x(\delta^{\uparrow}(v)) > \epsilon_F$. Now recall that from (24),

$$\sum_{\mathbf{f} \in \delta^{\to}(u)} m_{\mathbf{f},u} = Z_u \delta^{\uparrow}(u) \tag{34}$$

where $Z_u = 1 + \mathbb{I}\{|S| \ge 4, x(\delta^{\uparrow}(u)) \le \epsilon_F\}$. In this case, $Z_u = Z_v = 1$.

Using $\mathbb{P}\left[\mathcal{R}_{\mathbf{f},u'},\delta(u)_T \text{ odd}\right] = p\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},u'}\right]$, and plugging (32) into (33) for u and v, we get (and using Eq. (34)):

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] + \mathbb{E}\left[I_{\mathbf{e},v}\right] \leq p\tau \left(1 - \frac{\epsilon_{1/1}}{5}\right) \left(x(\delta^{\uparrow}(u))F_{u}\frac{m_{\mathbf{e},u}}{x(\delta^{\uparrow}(u))} + x(\delta^{\uparrow}(v))F_{v}\frac{m_{\mathbf{e},v}}{x(\delta^{\uparrow}(v))}\right)$$

$$= p\tau \left(1 - \frac{\epsilon_{1/1}}{5}\right) \left(F_{u}m_{\mathbf{e},u} + F_{v}m_{\mathbf{e},v}\right)$$

$$\leq p\tau \left(1 - \frac{\epsilon_{1/1}}{5}\right) \left(1 + 2\epsilon_{\eta}\right)x_{\mathbf{e}} < p\tau x_{\mathbf{e}} \left(1 - \frac{\epsilon_{1/1}}{6}\right).$$
(35)

where on the final line we used (23) and $\epsilon_{\eta} < \frac{\epsilon_{1/1}}{100}$.

Proof of Lemma 7.3. Suppose that $S_i \in \mathcal{H}$ are the ancestors of S in the hierarchy (in order) such $S_1 = S$ and for each i, $S_{i+1} = p(S_i)$. Let

$$\delta^{\geq i} := \delta(u) \cap \delta(S_i)$$
 and $\delta^i := \delta(u) \cap \delta^{\rightarrow}(S_i)$.

Each group of edges δ^i is either entirely top edges or entirely bottom edges. First note that if $g \in \delta^i$ and g is a bottom edge, i.e., S_{i+1} is a polygon cut, then by Corollary 5.10,

$$\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{S_{i+1}}\right] = \mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{E}_{S_{i+1}}\right] \leq 0.5678$$

(see Definition 5.8 and Item i) for definition of $\mathcal{E}_{S_{i+1}}$, \mathcal{R}_{i+1}) where in the equality we used that $\mathcal{R}_{S_{i+1}}$ is a uniformly random event chosen in $\mathcal{E}_{S_{i+1}}$. Therefore, to prove Eq. (32) it is enough to show

$$\sum_{\substack{g \in \delta_{\text{good}}^{\uparrow}(u): \\ g \in \mathbf{f} = (u',v') \text{ top,}}} \frac{1}{2} \tau x_g(\mathbb{P}\left[\delta(u)_T \text{ odd} \middle| \mathcal{R}_{\mathbf{f},u'}\right] + \mathbb{P}\left[\delta(u)_T \text{ odd} \middle| \mathcal{R}_{\mathbf{f},v'}\right])$$

$$\leq \tau \left(\left(1 - \frac{\epsilon_{1/1}}{5} \right) F_u \left(x(\delta_{\text{good}}^{\uparrow}(u)) + x(\delta_{\text{bad}}^{\uparrow}(u)) \right) + 0.0014 x(\delta_{\beta}^{\uparrow}(u)) \right) \tag{36}$$

where we write $\delta_{\beta}(u)$, $\delta_{\text{good}}(u)$, $\delta_{\text{bad}}(u)$ to denote the set of bottom edges, good top edges, and bad (top) edges in $\delta(u)$ respectively and we used that

$$\tau(1 - \frac{\epsilon_{1/1}}{5})(1 - \epsilon_B) - 0.5678\beta \ge 0.0014\tau$$

since $\tau = 0.571\beta$ and $\epsilon_{1/1} \le \frac{\epsilon_{1/2}}{12}$ and $\epsilon_{1/2} \le 0.0002$.

Since $h(\mathbf{f}) := \frac{1}{2} (\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},u'}\right] + \mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},v'}\right]) \le 1$ and $(1 - \frac{\epsilon_{1/1}}{5})F_u$ is nearly 1, in each of the following cases

$$x(\delta_{\beta}^{\uparrow}(u)) \ge \begin{cases} 0.003 & \text{when } F_u = 1\\ \frac{4}{5}x(\delta^{\uparrow}(u)) & \text{when } F_u = 1 - \epsilon_B \end{cases} \quad \text{or} \quad x(\delta_{\text{bad}}^{\uparrow}(u)) \ge 0.006 \quad \text{when } F_u \ge 1 - \epsilon_B,$$
(37)

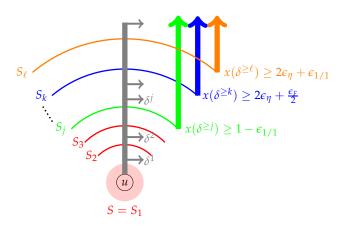

(36) holds. To see this, just plug in $\epsilon_{1/1} \le \frac{\epsilon_{1/2}}{12}$, $\epsilon_{1/2} \le 0.0002$, $\epsilon_B = 21\epsilon_{1/2}$, $\epsilon_\eta \le 10^{-10}$, $x(\delta^\uparrow(u)) \le 1 + \epsilon_\eta$ and any inequality from (37) into (36), using the upper bound $h(\mathbf{f}) = 1$.

Alternatively, for $\delta_{\text{top}}(u) = \delta_{\text{good}}(u) \cup \delta_{\text{bad}}(u)$ be the set of top edges in $\delta(u)$, if we can show the existence of a set $D \subseteq \delta_{\text{top}}^{\uparrow}(u)$ such that

$$x(D) \cdot \max_{\substack{g \in D: \\ g \in \mathbf{f} = (u', v') \text{ good}}} 1 - \frac{\mathbb{P}\left[\delta(u)_T \text{ odd} \middle| \mathcal{R}_{\mathbf{f}, u'}\right] + \mathbb{P}\left[\delta(u)_T \text{ odd} \middle| \mathcal{R}_{\mathbf{f}, v'}\right]}{2} \ge \left(\frac{\epsilon_{1/1}}{5} + 1 - F_u\right) x(\delta_{\text{top}}^{\uparrow}(u)),$$
(38)

then, again, (36) holds.

In the rest of the proof, we will consider a number of cases and show that in each of them, either one of the inequalities in (37) or the inequality in (38) for some set D is true, which will imply the lemma.

First, let

$$\begin{split} j &= \max\{i: x(\delta^{\geq i}) \geq 1 - \epsilon_{1/1}\} \\ k &= \max\{i: x(\delta^{\geq i}) \geq 2\epsilon_{\eta} + \epsilon_{F}/2\}, \\ \ell &= \max\{i: x(\delta^{\geq i}) \geq 2\epsilon_{\eta} + \epsilon_{1/1}\} \end{split}$$

Just note $j \le k \le \ell$. Note that levels ℓ and k exist since $x(\delta^{\uparrow}(u)) \ge \epsilon_F$, whereas level j may not exist (if $x(\delta^{\uparrow}(u)) < 1 - \epsilon_{1/1}$). We consider three cases:

Case 1: $x(\delta^{\uparrow}(u)) \geq 1 - \epsilon_{1/1}$: Then j exists and S_j has a valid A, B, C degree partitioning (Definition 5.18) where $A = \delta(u') \cap \delta(S_j)$ such that either u = u' or u' is a descendant of u in \mathcal{H} . Note that, $x(\delta(u) \cap \delta(S_j)) \geq 1 - \epsilon_{1/1}$, and that, in this case, $x(\delta^{\uparrow}(u))$ is not ϵ_F fractional (see Lemma 6.2), so $F_u = 1$.

Case 1a: $x(\delta^j) \ge 3/4$. If δ^j are bottom edges then (37) holds. So, suppose that δ^j is a set of top edges. By Lemma 5.28, at most $1/2 + 4\epsilon_{1/2}$ fraction of edges in $A \cap \delta^j$ are good but not 2-1-1 good (w.r.t., u). So, the rest of the edges in $A \cap \delta^j$ are either bad or 2-1-1 good. Since

$$x(A \cap \delta^j) \ge 3/4 - x(C) \ge 3/4 - 2\epsilon_{1/1} - \epsilon_{\eta},$$

 δ^j either has a mass of $\frac{1}{2}(1/4 - 2\epsilon_{1/1} - \epsilon_{\eta} - 4\epsilon_{1/2}) > 1/8 - 3\epsilon_{1/2}$ of bad edges or of 2-1-1 good edges.¹³ The former case implies that (37) holds. In the latter case, by Claim 7.4 for any 2-1-1 good edge $g \in \delta^j$ with $g \in \mathbf{f} = (u', v')$ we have $\mathbb{P}\left[\delta(u)_T \text{ odd} \middle| \mathcal{R}_{\mathbf{f}, u'}\right] \leq 2\epsilon_{\eta} + \epsilon_{1/1}$; so (38) holds for D defined as the set of 2-1-1 good edges in δ^j .

Case 1b: $x(\delta^j) < 3/4$. If $x(\delta^{\uparrow}_{\beta}(u)) \ge 0.003$, then (37) holds. Otherwise, we apply Claim 7.5 with $\epsilon = \epsilon_{1/1}$ to all top edges in $D = \delta^{\ge j+1} \setminus \delta^{\ge \ell+1}$ and we get that

$$\frac{1}{2}(\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},u'}\right] + \mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},v'}\right]) \leq 1 - \epsilon_{1/1} + \epsilon_{1/1}^2.$$

Since $x(D) \ge 1 - \epsilon_{1/1} - 3/4 - 2\epsilon_{\eta} - \epsilon_{1/1} - 0.003 > 0.24$, (38) holds.

Case 2: $1 - \epsilon_F < x(\delta^{\uparrow}(u)) < 1 - \epsilon_{1/1}$. Again we have $F_u = 1$. So we can either show that $x(\delta^{\uparrow}_{\beta}(u)) \ge 0.003$ or take D to be the top edges in $\delta^{\uparrow}(u) \setminus \delta^{\ge \ell+1}$ and use Claim 7.5 with $\epsilon = \epsilon_{1/1}$. This will enable us to show that (38) holds as in the previous case.

Case 3: $\epsilon_F < x_{\delta^{\uparrow}(u)} < 1 - \epsilon_F$: In this case $F_u = 1 - \epsilon_B$. If at least 4/5 of the edges in $\delta^{\uparrow}(u)$ are bottom edges, then we are done by (37).

Otherwise, let u' = p(u). For any top edge $e \in \delta^{\uparrow}(u)$ where $e \in \mathbf{f} = (u'', v'')$ we have

$$\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{\mathbf{f},u''}\right] \leq \mathbb{P}\left[u' \text{ tree}|\mathcal{R}_{\mathbf{f},u''}\right] \mathbb{P}\left[\delta(u)_T \text{ odd}|u' \text{ tree}, \mathcal{R}_{\mathbf{f},u''}\right] + \mathbb{P}\left[u' \text{ not tree}|\mathcal{R}_{\mathbf{f},u''}\right]$$

Using that $u' \subseteq u''$ is a tree under $|\mathcal{R}_{\mathbf{f},u''}$ with probability at least $1 - \epsilon_{\eta}/2$, and applying Claim 7.5 (to u and u') with $\epsilon = \epsilon_F$ we have $\mathbb{P}\left[\delta(u)_T \text{ odd}|u' \text{ tree}, \mathcal{R}_{\mathbf{f},u''}\right] \leq 1 - \epsilon_F + \epsilon_F^2$ we get

$$\mathbb{P}\left[\delta(u)_T \text{ odd} \middle| \mathcal{R}_{\mathbf{f},u''}\right] \leq 1 - \epsilon_F + \epsilon_F^2 + \epsilon_\eta/2.$$

Now, let D be all top edges in $\delta^{\uparrow}(u)$. Then, we apply Eq. (38) to this set of mass at least $x(\delta^{\uparrow}(u))/5$, and we are done, using that $(\epsilon_F - 2\epsilon_F^2)/5 \ge (\frac{\epsilon_{1/1}}{5} + \epsilon_B)$ which holds for $\epsilon_F \ge 1/10$, $\epsilon_B = 21\epsilon_{1/2}$, and $\epsilon_{1/2} \le 0.0002$.

Claim 7.4. For $u \in \mathcal{H}$ and a top edge $e \in \mathbf{f} = (u', v')$ for some $u' \in \mathcal{H}$ that is an ancestor of u, if $x(\delta(u) \cap \delta(u')) \ge 1 - \epsilon_{1/1}$ and \mathbf{f} is 2-1-1 good, then

$$\mathbb{P}\left[\delta(u)_T \ odd \middle| \mathcal{R}_{\mathbf{f},u'}\right] \leq 2\epsilon_{\eta} + \epsilon_{1/1}.$$

Proof. Let A, B, C be the degree partitioning of $\delta(u')$. By the assumption of the claim, without loss of generality, assume $A \subseteq \delta(u) \cap \delta(u')$. This means that if $\mathcal{R}_{\mathbf{f},u'} = 1$ then u' is a tree and $A_T = 1 = (\delta(u) \cap \delta(u'))_T$ (also using $C_T = 0$). Therefore,

$$\mathbb{P}\left[\delta(u)_T \text{ odd} \middle| \mathcal{R}_{\mathbf{f},u'}\right] = \mathbb{P}\left[\left(\delta(u) \setminus \delta(u')\right)_T \text{ even} \middle| \mathcal{R}_{\mathbf{f},u'}\right].$$

To upper bound the RHS first observe that

$$\mathbb{E}\left[\left(\delta(u) \setminus \delta(u')\right)_T | \mathcal{R}_{\mathbf{f},u'}\right] \leq \epsilon_{\eta}/2 + x(\delta(u) \setminus \delta(u')) \leq \epsilon_{\eta}/2 + x(\delta(u)) - x(A) < 1 + 2\epsilon_{\eta} + \epsilon_{1/1}.$$

¹³We are using the fact that $\epsilon_{1/1}=\epsilon_{1/2}/12$ and that ϵ_{η} is tiny by comparison to these.

Under the conditional measure $|\mathcal{R}_{f,u'}, u'|$ is a tree , so u must be connected inside u', i.e., $(\delta(u) \setminus \delta(u'))_T \ge 1$ with probability 1. Therefore,

$$\mathbb{P}\left[(\delta(u) \setminus \delta(u'))_T \text{ even} | \mathcal{R}_{\mathbf{f},u'}\right] \leq \mathbb{P}\left[(\delta(u) \setminus \delta(u'))_T - 1 \neq 0 | \mathcal{R}_{\mathbf{f},u'}\right] \leq 2\epsilon_{\eta} + \epsilon_{1/1}$$

as desired.

Claim 7.5. For $u, u' \in \mathcal{H}$ such that u' is an ancestor of u. Let $v = v_{u'} \times v_{G/u'}$ be the measure resulting from conditioning u' to be a tree. if $x(\delta(u) \cap \delta(u')) \in [\epsilon, 1 - \epsilon]$, then

$$\mathbb{P}_{\nu}\left[\delta(u) \ odd | (\delta(u) \cap \delta(u'))_{T}\right] \leq 1 - \epsilon + \min\{2\epsilon_{\eta}, \epsilon^{2}\}. \tag{39}$$

Proof. Let $D = \delta(u) \setminus \delta(u')$. By assumption, u' is a tree, so $D_T \ge 1$ with probability 1. Therefore, since we have no control over the parity of $(\delta(u) \cap \delta(u'))_T$

$$\mathbb{P}_{v}\left[\delta(u)_{T} \operatorname{even}\left|\left(\delta(u) \cap \delta(u')\right)_{T}\right| \geq \min\left\{\mathbb{P}\left[D_{T} - 1 \operatorname{odd}\left|u'\right| \operatorname{tree}\right], \mathbb{P}\left[D_{T} - 1 = 0\right|u'\right]\right\}$$

where we removed the conditioning by taking the worst case over $(\delta(u) \cap \delta(u'))_T$ even, $(\delta(u) \cap \delta(u'))_T$ odd. First, observe by the assumption of the claim and that $x(\delta^{\uparrow}(u)) \leq 2 + \epsilon_{\eta}$ we have

$$\mathbb{E}\left[D_T - 1|u' \text{ tree}\right] \in [\epsilon, 1 - \epsilon + 2\epsilon_{\eta}].$$

Furthermore, since we have a SR distribution on G[u'], $D_T - 1$ is a Bernoulli sum random variable. Therefore,

$$\mathbb{P}\left[D_T - 1 = 0 | u' \text{ tree}\right] \ge \epsilon - 2\epsilon_{\eta}$$

and by Corollary 2.17

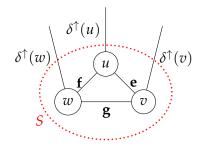

$$\mathbb{P}\left[D_T - 1 \text{ odd}|u' \text{ tree}\right] \ge 1 - 1/2(1 + e^{-2\epsilon}) \ge \epsilon - \epsilon^2$$

as desired.

Lemma 7.6. Let $S \in \mathcal{H}$ be a degree cut and $\mathbf{e} = (u, v)$ a good edge bundle with $p(\mathbf{e}) = S$. If $x(\delta^{\uparrow}(u)) < \epsilon_F$, $\epsilon_{1/2} \le 0.0002$, $\epsilon_{1/1} \le \epsilon_{1/2}/10$, then,

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] + \mathbb{E}\left[I_{\mathbf{e},v}\right] \le p\tau x_{\mathbf{e}} \left(1 - \frac{\epsilon_{1/1}}{6}\right)$$

Proof. First, we consider the case $|\mathcal{A}(S)| = 3$, where $\mathcal{A}(S) = \{u, v, w\}$. Let $\mathbf{f} = (u, w)$, $\mathbf{g} = (v, w)$ (and of course $\mathbf{e} = (u, v)$). We will use the following facts below:

$$x_{\mathbf{e}} + x_{\mathbf{f}} \ge 2 - \epsilon_F$$
 $(x(\delta(u)) \ge 2 \text{ and } x(\delta^{\uparrow}(u)) \le \epsilon_F)$ $x(\delta^{\uparrow}(v)) + x(\delta^{\uparrow}(w)) \ge 2 - \epsilon_F$ $(x(\delta(S)) \ge 2)$ $x_{\mathbf{f}}, x(\delta^{\uparrow}(w)) \le 1 + \epsilon_n,$ (Lemma 2.7)

so we have,

$$x_{\mathbf{e}}, x(\delta^{\uparrow}(v)) \ge 1 - \epsilon_F - \epsilon_{\eta}.$$
 (40)

Now we bound $\mathbb{E}[I_{\mathbf{e},u}] + \mathbb{E}[I_{\mathbf{e},v}]$. Since $x(\delta^{\uparrow}(v)) \ge \epsilon_F$, applying (32) and (33) to $I_{\mathbf{e},v}$ and using $Z_v = 1$ we get

$$\mathbb{E}\left[I_{\mathbf{e},v}\right] \le \frac{m_{\mathbf{e},v}}{\sum_{\mathbf{f} \in \delta^{\to}(v)} m_{\mathbf{f},v}} p\tau \left(1 - \frac{\epsilon_{1/1}}{5}\right) x(\delta^{\uparrow}(v)) F_v = m_{\mathbf{e},v} p\tau \left(1 - \frac{\epsilon_{1/1}}{5}\right) F_v \tag{41}$$

On the other hand, since by Corollary 5.10 for any bottom edge $g \in \delta^{\uparrow}(u)$ with p(g) = S', we have

$$\mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{R}_{S'}\right] = \mathbb{P}\left[\delta(u)_T \text{ odd}|\mathcal{E}_{S'}\right] \leq 0.5678,$$

using $0.5678\beta \le \tau$ and $Z_u = 1$ we can write,

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] \leq \sum_{h \in \delta^{\uparrow}(u)} x_h p \tau F_u \cdot \frac{m_{\mathbf{e},u}}{Z_u x(\delta^{\uparrow}(u))} = p \tau F_u m_{\mathbf{e},u}. \tag{42}$$

Therefore,

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] + \mathbb{E}\left[I_{\mathbf{e},v}\right] \leq p\tau F_{u} m_{\mathbf{e},u} + p\tau \left(1 - \frac{\epsilon_{1/1}}{5}\right) F_{v} m_{\mathbf{e},v}$$

$$= p\tau (F_{u} m_{\mathbf{e},u} + F_{v} m_{\mathbf{e},v}) - \frac{\epsilon_{1/1}}{5} p\tau F_{v} m_{\mathbf{e},v}$$

$$\leq p\tau (1 + 2\epsilon_{\eta}) x_{\mathbf{e}} - \frac{\epsilon_{1/1}}{5} p\tau F_{v} m_{\mathbf{e},v}$$

$$(43)$$

where the final inequality follows from (23). To complete the proof, we lower bound $m_{e,v}$. Using (24) for v and w, we can write,

$$x(\delta^{\uparrow}(v)) + x(\delta^{\uparrow}(w)) = m_{\mathbf{e},v} + m_{\mathbf{g},v} + m_{\mathbf{f},w} + m_{\mathbf{g},w}$$

$$\leq m_{\mathbf{e},v} + \frac{(1+2\epsilon_{\eta})}{(1-\epsilon_{B})} (x_{\mathbf{f}} + x_{\mathbf{g}}) \qquad \text{(using (23))}$$

$$= m_{\mathbf{e},v} + \frac{(1+2\epsilon_{\eta})}{(1-\epsilon_{B})} \left(\sum_{a \in \mathcal{A}(S)} \frac{x(\delta(a))}{2} - \frac{x(\delta(S))}{2} - x_{\mathbf{e}} \right)$$

$$\leq m_{\mathbf{e},v} + \frac{(1+2\epsilon_{\eta})}{(1-\epsilon_{B})} (2+3\epsilon_{\eta} - x_{\mathbf{e}})$$

and using the fact that $x(\delta^{\uparrow}(v)) + x(\delta^{\uparrow}(w)) \ge 2 - \epsilon_F$, we get

$$m_{\mathbf{e},v} \geq x_{\mathbf{e}} - \epsilon_F - 4\epsilon_B \geq (1 - 1.2\epsilon_F)x_{\mathbf{e}},$$

where the second inequality follows from (40) and $\epsilon_B = 21\epsilon_{1/2}$ and $\epsilon_{\eta} < \epsilon_{1/2}^2$ and $\epsilon_F \ge 1/10$. Plugging this back into (43) and using $F_v \ge 1 - \epsilon_B = 1 - 21\epsilon_{1/2}$ we get

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] + \mathbb{E}\left[I_{\mathbf{e},v}\right] \leq p\tau x_{\mathbf{e}} \left(1 + 2\epsilon_{\eta} - \frac{\epsilon_{1/1}}{5}(1 - 1.2\epsilon_{F})(1 - 21\epsilon_{1/2})\right) \leq p\tau x_{\mathbf{e}}(1 - \frac{\epsilon_{1/1}}{6})$$

as desired. In the last inequality we used $\epsilon_F \leq 1/10$ and $\epsilon_{1/2} \leq 0.0002$.

Case 2: $|S| \ge 4$. In this case, $Z_u = 2$. Therefore, by Eq. (42)

$$\mathbb{E}\left[I_{\mathbf{e},u}\right] \leq \sum_{e \in \delta^{\uparrow}(u)} x_e p \tau F_u \frac{m_{\mathbf{e},u}}{Z_u x(\delta^{\uparrow}(u))} = \frac{1}{2} p \tau F_u m_{\mathbf{e},u}.$$

Now, either $x(\delta^{\uparrow}(v)) < \epsilon_F$ and we get the same inequality for $I_{\mathbf{e},v}$ or $x(\delta^{\uparrow}(v)) \ge \epsilon_F$ in which case by (41) we get $\mathbb{E}\left[I_{\mathbf{e},v}\right] \le m_{\mathbf{e},v}p\tau F_v(1-\epsilon_{1/1}/5)$. Putting these together proves the lemma.

7.2 Increase for Bottom Edges

The following lemma is the main result of this subsection.

Lemma 7.7 (Bottom Edge Increase). *If* $\epsilon_{1/2} \leq 0.0002$, $\epsilon_{\eta} \leq \epsilon_{1/2}^2$, for any polygon cut $S \in \mathcal{H}$,

$$\mathbb{E}[I_S] \leq 0.99994\beta p.$$

Proof. For a set of edges $D \in \delta(S)$ define the random variable.

$$I_{S}(D) := (1 + \epsilon_{\eta}) (\max\{r(A \cap D)\mathbb{I} \{S \text{ not left happy}\}, r(B \cap D)\mathbb{I} \{S \text{ not right happy}\} + r(C \cap D)\mathbb{I} \{S \text{ not happy}\}).$$

$$(44)$$

Note that by definition $I_S(\delta(S)) = I_S$ and for any two disjoint sets $D_1, D_2, I_S(D_1 \cup D_2) \leq I_S(D_1) + I_S(D_2)$. Also, define $I_S^{\uparrow} = I_S(\delta^{\uparrow}(S))$ and $I_S^{\rightarrow} = I_S(\delta^{\rightarrow}(S))$.

First, we upper bound $\mathbb{E}\left[I_S^{\uparrow}\right]$. Let $f \in \delta^{\uparrow}(S)$ and suppose that f with p(f) = S' is a bottom edge. Say we have $f \in A^{\uparrow}(S)$. We write,

$$\mathbb{E}\left[I_{S}(f)\right] = (1 + \epsilon_{\eta})\beta x_{f} \mathbb{P}\left[\mathcal{R}_{S'}\right] \mathbb{P}\left[S \text{ not left happy } |\mathcal{R}_{S'}\right] \\ \leq 0.568 x_{f} p\beta$$

where in the inequality we used Corollary 5.11 and that

$$\mathbb{P}[S \text{ not left happy} | \mathcal{R}_S] = \mathbb{P}[S \text{ not left happy} | \mathcal{E}_S]$$

since \mathcal{R}_S is a uniformly random subset of \mathcal{E}_S . On the other hand, if f is a top edge, then we use the trivial bound

$$\mathbb{E}\left[I_S(f)\right] = (1 + \epsilon_{\eta})\tau p x_f. \tag{45}$$

Therefore,

$$\mathbb{E}\left[I_S^{\uparrow}\right] \le (1 + \epsilon_{\eta}) \tau px(\delta^{\uparrow}(S)) \le (1 + \epsilon_{\eta})(0.571) \beta px(\delta^{\uparrow}(S)) \tag{46}$$

Now, we consider three cases:

Case 1: $\hat{S} = p(S)$ is a degree cut. Combining (46) and Lemma 7.8 below, we get

$$\mathbb{E}\left[I_S\right] \le (1 + \epsilon_{\eta})p(0.571)\beta(7/4 + 6\epsilon_{1/2} + \epsilon_{\eta}) \le 0.99994\beta p$$

using $\epsilon_{1/2} \leq 0.0002$ and $\epsilon_{\eta} \leq \epsilon_{1/2}^2$.

Case 2: $\hat{S} = p(S)$ is a polygon cut with ordering u_1, \dots, u_k of $\mathcal{A}(\hat{S})$, $S = u_1$ or $S = u_k$ Then, by Lemma 7.9 below,

$$\mathbb{E}[I_S] \le (1 + \epsilon_{\eta})\beta p(0.571x(\delta^{\uparrow}) + 0.31) \le 0.89\beta p$$

where we used $x(\delta^{\uparrow}(S)) \leq 1 + \epsilon_{\eta}$.

Case 3: $\hat{S} = p(S)$ is a polygon cut with ordering u_1, \dots, u_k of $\mathcal{A}(\hat{S})$, $S \neq u_1, u_k$ Then, by Lemma 7.12 below

$$\mathbb{E}\left[I_S\right] \le (1 + \epsilon_{\eta})\beta p(0.571x(\delta^{\uparrow}) + 0.85) \le 0.86\beta p$$

where we use that $x(\delta^{\uparrow}(S)) \leq \epsilon_{\eta}$ since we have a hierarchy. This concludes the proof.

7.2.1 Case 1: \hat{S} is a degree cut

Lemma 7.8. Let $S \in \mathcal{H}$ be a polygon cut with parent \hat{S} which is a degree cut. Then

$$\mathbb{E}\left[I_S^{\to}\right] \leq (1 + \epsilon_{\eta}) p \tau(x(\delta^{\to}(S)) - (1/4 - 6\epsilon_{1/2})).$$

Proof. Let A, B, C be the polygon partition of S. We will show that for a constant fraction of the edges in $\delta^{\rightarrow}(S)$, we can improve over the trivial bound in (45). To this end, consider the cases given by Theorem 5.21.

Case 1: There is a set of 2-1-1 good edges (w.r.t., S) $D \subseteq \delta^{\rightarrow}(S)$, such that $x_D \ge 1/2 - \epsilon_{1/2} - \epsilon_{\eta}$. For any (top) edge $e \in \mathbf{f} = (S, u)$ such that $e \in D$, if $\mathcal{R}_{\mathbf{f},S}$, then S is happy, that is $A_T = B_T = 1$, $C_T = 0$.

Therefore,

$$\mathbb{E}\left[I_{S}(D)\right] \leq \sum_{e \in D: e \in \mathbf{f}=(S,u)} \frac{1+\epsilon_{\eta}}{2} \tau x_{e} \mathbb{P}\left[S \text{ not happy} | \mathcal{R}_{\mathbf{f},u}\right] \mathbb{P}\left[\mathcal{R}_{\mathbf{f},u}\right]$$
$$\leq \frac{1+\epsilon_{\eta}}{2} p \tau x(D).$$

Using the trivial inequality Eq. (45) for edges in $\delta^{\rightarrow}(S) \setminus D$ we get

$$\mathbb{E}\left[I_S^{\rightarrow}\right] \leq (1 + \epsilon_{\eta})p\tau(\frac{x(D)}{2} + x(\delta^{\rightarrow}(S)) - x(D)) \leq (1 + \epsilon_{\eta})p\tau(x(\delta^{\rightarrow}(S)) - (1/4 - \epsilon_{1/2}))$$

as desired. In the last inequality we used $x(D) \ge 1/2 - \epsilon_{1/2} - \epsilon_{\eta}$.

Case 2: There are two 2-2-2 good top half edge bundles, $\mathbf{e}=(S,v)$, $\mathbf{f}=(S,w)$ in $\delta^{\rightarrow}(S)$, such that $x_{\mathbf{e}(B)}, x_{\mathbf{f}(A)} \leq \epsilon_{1/2}$. (Recall that $\mathbf{e}(A) = \mathbf{e} \cap A$.) Let $D = \mathbf{e}(A) \cup \mathbf{f}(B)$. In this case, \mathbf{e} and \mathbf{f} are reduced simultaneously by τ when they are 2-2-2 happy (w.r.t., S), i.e., when $\mathcal{R}_{\mathbf{e},S} = \mathcal{R}_{\mathbf{f},S} = 1$. In such a case we have $\delta(S)_T = \delta(v)_T = \delta(w)_T = 2$. Therefore,

$$\begin{split} \mathbb{E}\left[I_{S}(D)\right] &\leq (1+\epsilon_{\eta})\mathbb{E}\left[\max\{r(A\cap D), r(B\cap D)\}\right] \\ &\leq (1+\epsilon_{\eta})\frac{\tau}{2}\max\{x_{\mathbf{e}(A)}, x_{\mathbf{f}(B)}\}(\mathbb{P}\left[\mathbf{e}, \mathbf{f} \text{ 2-2-2 happy}\right] + \mathbb{P}\left[\mathcal{R}_{\mathbf{e}, v}\right] + \mathbb{P}\left[\mathcal{R}_{\mathbf{f}, w}\right]) \\ &\leq (1+\epsilon_{\eta})\tau\frac{3p}{2}x(D)\left(\frac{1}{2}+3\epsilon_{1/2}\right) = (1+\epsilon_{\eta})\tau px(D)\left(\frac{3}{4}+4.5\epsilon_{1/2}\right) \end{split}$$

where we used that $1/2 - 2\epsilon_{1/2} - x(C) \le x_{\mathbf{e}(A)}$, $x_{\mathbf{f}(B)} \le 1/2 + \epsilon_{1/2}$ and that $x(C) \le \epsilon_{\eta}$. Using the trivial inequality Eq. (45) for edges in $\delta^{\to}(S) \setminus D$ we get

$$\mathbb{E}\left[I_{S}^{\to}\right] \leq (1 + \epsilon_{\eta}) p \tau(x(D)(3/4 + 4.5\epsilon_{1/2}) + x(\delta^{\to}(S)) - x(D))$$

$$\leq (1 + \epsilon_{\eta}) p \tau(x(\delta^{\to}(S)) - (1/4 - 6\epsilon_{1/2}))$$

where we used $x(D) \ge 1 - 4\epsilon_{1/2} - \epsilon_{\eta}$.

Case 3: There is a bad half edge e in $\delta^{\rightarrow}(S)$. Since bad edges never decrease, no corresponding increase occurs, so by the trivial bound Eq. (45)

$$\mathbb{E}\left[I_S^{\to}\right] \leq (1 + \epsilon_{\eta}) p \tau(x(\delta^{\to}(S)) - (1/2 - \epsilon_{1/2})).$$

This concludes the proof.

7.2.2 Case 2: S and its parent \hat{S} are both polygon cuts

In this subsection we prove two lemmas: Lemma 7.9, which bounds $\mathbb{E}\left[I_{S}^{\rightarrow}\right]$ when S is the leftmost or rightmost atom of \hat{S} , and Lemma 7.12, which bounds this quantity when S is not leftmost or rightmost.

Lemma 7.9. Let $S \in \mathcal{H}$ be a polygon cut with $p(S) = \hat{S}$ also a polygon cut. Let u_1, \ldots, u_k be the ordering of cuts in $\mathcal{A}(\hat{S})$ (as defined in Definition 4.31). If $\epsilon_M \leq 0.001$, $\epsilon_\eta \leq \epsilon_M^2$, $S = u_1$ or $S = u_k$, then

$$\mathbb{E}\left[I_S^{\rightarrow}\right] \leq 0.31\beta p.$$

Proof. Let *S* be the leftmost atom of \hat{S} and let *A*, *B*, *C* be the polygon partition of $\delta(S)$. First, note

$$\mathbb{E}\left[I_S^{\rightarrow}\right] \leq (1 + \epsilon_{\eta}) \left(\mathbb{E}\left[\max(r(A^{\rightarrow}), r(B^{\rightarrow})) \cdot \mathbb{I}\left\{S \text{ not happy}\right\}\right] + \mathbb{E}\left[r(C^{\rightarrow})\mathbb{I}\left\{S \text{ not happy}\right\}\right]\right). \tag{47}$$

where recall that $A^{\rightarrow}=A\cap\delta^{\rightarrow}(S)$. WLOG assume $x(A^{\rightarrow})\geq x(B^{\rightarrow})$. Then,

$$\mathbb{E}\left[\max\{r(A^{\rightarrow}), r(B^{\rightarrow})\}\mathbb{I}\left\{S \text{ not happy}\right\}\right] = \beta px(A^{\rightarrow}) \cdot \mathbb{P}\left[S \text{ not happy}|\mathcal{R}_{\hat{S}}\right]$$

By Lemma 7.10 we have

$$\begin{split} x(A^{\rightarrow}) \cdot \mathbb{P}\left[S \text{ not happy} | \mathcal{R}_{\hat{S}}\right] &\leq x(A^{\rightarrow}) \left(1 - ((1 - x(A^{\rightarrow}))^2 + (x(A^{\rightarrow}))^2 - 2\epsilon_M - 17\epsilon_{\eta})\right) \\ &\leq \left(2x(A^{\rightarrow})^2 - 2x(A^{\rightarrow})^3 + 2\epsilon_M x(A^{\rightarrow}) + 17\epsilon_{\eta} x(A^{\rightarrow})\right) \\ &\leq \left(8/27 + 2\epsilon_M + 17\epsilon_{\eta}\right), \end{split}$$

where in the final inequality we used that the function $x \mapsto x^2(1-x)$ is maximized at x=2/3, and using $\epsilon_M \leq 0.001$, $\epsilon_\eta < \epsilon_M^2$.

Plugging this back into (47), and using $x(C) \le \epsilon_{\eta}$, we get

$$\mathbb{E}\left[I_S^{\rightarrow}\right] \leq (1 + \epsilon_{\eta})\beta p(\frac{8}{27} + 2\epsilon_M + 18\epsilon_{\eta}) \leq 0.31\beta p,$$

where the last inequality follows since $\epsilon_M \leq 0.001$ and $\epsilon_{\eta} < \epsilon_M^2$.

Lemma 7.10. Let $S \in \mathcal{H}$ be a polygon cut with $p(S) = \hat{S}$ also a polygon cut. Let u_1, \ldots, u_k be the ordering of cuts in $\mathcal{A}(\hat{S})$. If $S = u_1$, (or $S = u_k$) then

$$\mathbb{P}\left[S \ happy | \mathcal{R}_{\hat{S}}\right] \ge (1 - x(A^{\to}))^2 + (x(A^{\to}))^2 - 2\epsilon_M - 17\epsilon_{\eta}.$$

Proof. Let $A, B, C, \hat{A}, \hat{B}, \hat{C}$ be the polygon partition of S, \hat{S} respectively. Observe that since $S = u_1$, we have $\hat{A} = E(u_1, \overline{\hat{S}}) = A^{\uparrow} \cup B^{\uparrow} \cup C^{\uparrow}$ and $\hat{B}, \hat{C} \cap (A \cup B \cup C) = \emptyset$. Conditioned on $\mathcal{R}_{\hat{S}}, \hat{S}$ is a tree, and marginals of all edges in \hat{A} is changed by a total variation distance at most $\epsilon'_M := \epsilon_M + 2\epsilon_\eta$ from x (see Corollary 5.9) and they are independent of edges inside \hat{S} . The tree conditioning increases marginals inside by at most $\epsilon_{\eta}/2$. Since after the changes just described

$$\mathbb{E}\left[C_T\right] \leq x_C + \epsilon_{\eta} + \epsilon_M' \leq 4\epsilon_{\eta} + \epsilon_M,$$

it follows that $\mathbb{P}\left[C_T = 0 | \mathcal{R}_{\hat{S}}\right] \geq 1 - 4\epsilon_{\eta} - \epsilon_{M}$. So,

$$\mathbb{P}\left[S \text{ happy } \mid \mathcal{R}_{\hat{S}}\right] \ge (1 - 4\epsilon_{\eta} - \epsilon_{M}) \mathbb{P}\left[A_{T} = B_{T} = 1 \middle| C_{T} = 0, \mathcal{R}_{\hat{S}}\right]. \tag{48}$$

Let ν be the conditional measure $C_T = 0$, $\mathcal{R}_{\hat{S}}$. We see that

$$\mathbb{P}_{\nu}\left[A_T=B_T=1\right]=\mathbb{P}_{\nu}\left[A_T^{\uparrow}=1,B_T^{\uparrow}=0,A_T^{\rightarrow}=0,B_T^{\rightarrow}=1\right]+\mathbb{P}_{\nu}\left[A_T^{\uparrow}=0,B_T^{\uparrow}=1,A_T^{\rightarrow}=1,B_T^{\rightarrow}=0\right]$$

so using independence of $(\delta^{\uparrow}(S))_T$ and $(\delta^{\rightarrow}(S))_T$.

$$= \mathbb{P}_{\nu} \left[A_{T}^{\uparrow} = 1, B_{T}^{\uparrow} = 0 \right] \mathbb{P}_{\nu} \left[A_{T}^{\rightarrow} = 0, B_{T}^{\rightarrow} = 1 \right] + \mathbb{P}_{\nu} \left[A_{T}^{\uparrow} = 0, B_{T}^{\uparrow} = 1 \right] \mathbb{P}_{\nu} \left[A_{T}^{\rightarrow} = 1, B_{T}^{\rightarrow} = 0 \right]$$

$$\geq (x(A^{\uparrow}) - \epsilon'_{M}) \mathbb{P}_{\nu} \left[A_{T}^{\rightarrow} = 0, B_{T}^{\rightarrow} = 1 \right] + (x(B^{\uparrow}) - \epsilon'_{M}) \mathbb{P}_{\nu} \left[A_{T}^{\rightarrow} = 1, B_{T}^{\rightarrow} = 0 \right].$$

In the final inequality, we used the fact that conditioned on $\mathcal{R}_{\hat{S}}$, $\hat{A}=(A^{\uparrow}\cup B^{\uparrow}\cup C^{\uparrow})_T=1$ and marginals in A^{\uparrow} and B^{\uparrow} are approximately preserved. Now, we lower bound $\mathbb{P}_{\nu}\left[A_T^{\rightarrow}=1,B_T^{\rightarrow}=0\right]$. Let ϵ_A , ϵ_B be such that

$$\mathbb{E}_{\nu}\left[A_{T}^{\rightarrow}\right] = \mathbb{P}_{\nu}\left[A_{T}^{\rightarrow} = 1, B_{T}^{\rightarrow} = 0\right] + \epsilon_{A}, \quad \mathbb{E}_{\nu}\left[B_{T}^{\rightarrow}\right] = \mathbb{P}_{\nu}\left[A_{T}^{\rightarrow} = 0, B_{T}^{\rightarrow} = 1\right] + \epsilon_{B}$$

Therefore,

$$\epsilon_{A} + \epsilon_{B} = \mathbb{E}_{\nu} \left[A_{T}^{\rightarrow} + B_{T}^{\rightarrow} \right] - \mathbb{P}_{\nu} \left[A_{T}^{\rightarrow} + B_{T}^{\rightarrow} = 1 \right] \le x(\delta(S)) - x(\delta^{\uparrow}(S)) + \epsilon_{\eta}
\le (2 + \epsilon_{\eta} + 1.5\epsilon_{\eta} - (1 - \epsilon_{\eta})) - (1 - 4\epsilon_{\eta}) \le 8\epsilon_{\eta}.$$

where in the inequality we used $x(\delta(S)) \leq 2 + \epsilon_{\eta}$, that conditioning \hat{S} to be a tree and C to 0 increases marginals by at most $1.5\epsilon_{\eta}$, that $x(\delta^{\uparrow}(S)) \geq 1 - \epsilon_{\eta}$ (by Lemma 4.17) and Claim 7.11. Therefore,

$$\mathbb{P}_{\nu}\left[A_{T} = B_{T} = 1\right] \ge (x(A^{\uparrow}) - \epsilon'_{M})(\mathbb{E}_{\nu}\left[B_{T}^{\rightarrow}\right] - \epsilon_{B}) + (x(B^{\uparrow}) - \epsilon'_{M})(\mathbb{E}_{\nu}\left[A_{T}^{\rightarrow}\right] - \epsilon_{A}) \\
\ge (x(A^{\uparrow}) - \epsilon'_{M})(x(B^{\rightarrow}) - 8\epsilon_{\eta}) + (x(B^{\uparrow}) - \epsilon'_{M})(x(A^{\rightarrow}) - 8\epsilon_{\eta})$$

where the second inequality uses that the tree conditioning and $C_T^{\rightarrow}=0$ can only increase the marginals of edges in A^{\rightarrow} and B^{\rightarrow} . Simplify the above using $x(A^{\uparrow})+x(A^{\rightarrow})\geq 1-\epsilon_{\eta}$, and similarly for B,

$$\begin{split} & \mathbb{P}_{\nu} \left[A_T = B_T = 1 \right] \\ & \geq (1 - x(A^{\to}) - \epsilon_{\eta} - \epsilon_M')(x(B^{\to}) - 8\epsilon_{\eta}) + (1 - x(B^{\to}) - \epsilon_{\eta} - \epsilon_M')(x(A^{\to}) - 8\epsilon_{\eta}) \end{split}$$

and since $x(A^{\to}) + x(B^{\to}) \ge 1 - 2\epsilon_{\eta}$ (because $x(A^{\uparrow}) + x(B^{\uparrow}) \le 1 + \epsilon_{\eta}$ and $x_C \le \epsilon_{\eta}$), this is

$$\geq (1 - x(A^{\rightarrow}) - \epsilon_{\eta} - \epsilon'_{M})(1 - x(A^{\rightarrow}) - 10\epsilon_{\eta}) + (x(A^{\rightarrow}) - 3\epsilon_{\eta} - \epsilon'_{M})(x(A^{\rightarrow}) - 8\epsilon_{\eta})$$

$$\geq (1 - x(A^{\rightarrow}))^{2} + (x(A^{\rightarrow}))^{2} - \epsilon'_{M} - 11\epsilon_{\eta}.$$

Plugging this into Eq. (48), we obtain

$$\mathbb{P}\left[A_{T} = B_{T} = 1, C_{T} = 0 \mid \mathcal{R}_{\hat{S}}\right] \geq (1 - 2\epsilon_{\eta} - \epsilon'_{M}) \mathbb{P}\left[A_{T} = B_{T} = 1 | C_{T} = 0, \mathcal{R}_{\hat{S}}\right] \\
\geq (1 - 2\epsilon_{\eta} - \epsilon'_{M}) ((1 - x(A^{\to}))^{2} + (x(A^{\to}))^{2} - \epsilon'_{M} - 11\epsilon_{\eta}) \\
\geq (1 - x(A^{\to}))^{2} + (x(A^{\to}))^{2} - 2\epsilon'_{M} - 13\epsilon_{\eta},$$

which noting $\epsilon_M' = \epsilon_M + 2\epsilon_\eta$ completes the proof of the lemma.

Claim 7.11. Let ν be the conditional measure $C_T = 0$, $\mathcal{R}_{\hat{S}}$. Then

$$\mathbb{P}_{\nu}\left[A_{T}^{\rightarrow}+B_{T}^{\rightarrow}=1\right]\geq1-4\epsilon_{\eta}.$$

Proof. First, notice under ν , \hat{S} is a tree, and $\delta^{\rightarrow}(S)$ is independent of edges in G/\hat{S} , though $\mathbb{E}_{\nu}\left[\delta^{\rightarrow}(S)_{T}\right]$ may be increased by $2\epsilon_{\eta}$ due to $\mathcal{R}_{\hat{S}}$, $C_{T}=0$, so

$$\mathbb{E}_{\nu}\left[\delta^{\to}(S)_{T}\right] \leq 2 + \epsilon_{\eta} - (1 - \epsilon_{\eta}) + 2\epsilon_{\eta} \leq 1 + 4\epsilon_{\eta},$$

where we used that $S = u_1$, so $x(\delta^{\uparrow}(S)) \ge 1 - \epsilon_{\eta}$.

Also, since $C_T = 0$, under ν , we have $\delta^{\rightarrow}(S)_T = A_T^{\rightarrow} + B_T^{\rightarrow}$. Furthermore, since $\delta^{\rightarrow}(S)_T \geq 1$ with probability 1 under ν ,

$$\mathbb{P}_{\nu}\left[A_{T}^{\rightarrow}+B_{T}^{\rightarrow}=1\right]=\mathbb{P}_{\nu}\left[\delta^{\rightarrow}(S)_{T}=1\right]\geq1-4\epsilon_{\eta}$$

as desired. \Box

Lemma 7.12. Let $S \in \mathcal{H}$ be a polygon cut with $p(S) = \hat{S}$ also a polygon cut with u_1, \ldots, u_k be the ordering of cuts in $\mathcal{A}(\hat{S})$. If $S \neq u_1, u_k$, then

$$\mathbb{E}\left[I_S^{\rightarrow}\right] \leq 0.85\beta p.$$

Proof. Let $S = u_i$ for some $2 \le i \le k-1$. Let A, B, C be the polygon partitioning of $\delta(u_i)$ and $\hat{A}, \hat{B}, \hat{C}$ be the polygon partition of \hat{S} . Since u_i is in the hierarchy $A^{\uparrow} \cup B^{\uparrow} \cup C^{\uparrow} \subseteq \hat{C}$. So, conditioned on $\mathcal{R}_{\hat{S}}$, $A_T^{\uparrow} = B_T^{\uparrow} = C_T^{\uparrow} = 0$.

Once again, let ν be the conditional measure $C_T = 0$, $\mathcal{R}_{\hat{S}}$. Similar to the previous case, we will lower-bound

$$\mathbb{P}\left[S \text{ happy}|\mathcal{R}_{\hat{S}}\right] \ge (1 - 2\epsilon_{\eta}) \mathbb{P}\left[A_{T}^{\rightarrow} = 1, B_{T}^{\rightarrow} = 1, |C_{T} = 0, \mathcal{R}_{\hat{S}}\right]
= (1 - 2\epsilon_{\eta}) \mathbb{P}_{\nu}\left[A_{T}^{\rightarrow} = 1|A_{T}^{\rightarrow} + B_{T}^{\rightarrow} = 2\right] \mathbb{P}_{\nu}\left[A_{T}^{\rightarrow} + B_{T}^{\rightarrow} = 2\right]$$
(49)

where we used $\mathbb{E}\left[C_T^{\rightarrow}|\mathcal{R}_{\hat{S}}\right] \leq 2\epsilon_{\eta}$ in the first inequality. So, it remains to lower-bound each of the two terms in the RHS.

We start with the first one. Since $x(A) \in [1 - \epsilon_{\eta}, 1 + \epsilon_{\eta}]$ and $x(A^{\uparrow}) \leq \epsilon_{\eta}$ we have

$$\mathbb{E}_{\nu}\left[A_{T}^{\rightarrow}\right]\in\left[1-2\epsilon_{\eta},1+3\epsilon_{\eta}\right].$$

The same bounds hold for $\mathbb{E}_{\nu}[x(B^{\rightarrow})]$.

Therefore,

$$\mathbb{P}_{\nu}\left[A_{T}^{\rightarrow} \geq 1\right]$$
, $\mathbb{P}_{\nu}\left[B_{T}^{\rightarrow} \geq 1\right] \geq 1 - e^{-1 + 2\epsilon_{\eta}}$ (Lemma 2.22)
 $\mathbb{P}_{\nu}\left[A_{T}^{\rightarrow} \leq 1\right]$, $\mathbb{P}_{\nu}\left[B_{T}^{\rightarrow} \leq 1\right] \geq 0.495$ (Markov)

Therefore, by Corollary 5.5 (with $\epsilon = 0.495(1 - e^{-1 + 2\epsilon_{\eta}}) \ge 0.31$) we have

$$\mathbb{P}_{\nu} [A_T^{\to} = 1 \mid A_T^{\to} + B_T^{\to} = 2] \ge 0.155.$$

By Corollary 2.24, $\mathbb{P}_{\nu}\left[E(u_{i-1},u_i)_T=1\right]\geq 1-4\epsilon_{\eta}$. Similarly, $\mathbb{P}_{\nu}\left[E(u_i,u_{i+1})_T=1\right]\geq 1-4\epsilon_{\eta}$. And,

$$\mathbb{P}_{\nu} \left[\delta^{\to}(u_i)_T - E(u_{i-1}, u_i)_T - E(u_i, u_{i+1})_T = 0 \right] \ge 1 - 4\epsilon_{\eta}$$

So, by a union bound all of these events happen simultaneously and we get $\mathbb{P}_{\nu}\left[\delta^{\to}(u_i)_T=2\right] \geq 1-12\epsilon_{\eta}$. Therefore,

$$\mathbb{P}_{\nu}\left[(A^{\to})_T = (B^{\to})_T = 1 \right] \ge 0.155(1 - 12\epsilon_{\eta}) \ge 0.153.$$

Plugging this back into (49), we get

$$\mathbb{P}\left[S \text{ happy} | \mathcal{R}_{\hat{S}}\right] \geq 0.153(1 - 2\epsilon_{\eta}) \geq 0.152.$$

Plugging this in (47) we get

$$\mathbb{E}\left[I_{S}^{\rightarrow}\right] \leq (1 + \epsilon_{\eta})\beta p \mathbb{P}\left[S \text{ not happy} | \mathcal{R}_{\hat{S}}\right] \left(\max\{x(A^{\rightarrow}), x(B^{\rightarrow})\} + x(C^{\rightarrow})\right) \\ \leq (1 + \epsilon_{\eta})\beta p (1 - 0.152)(1 + \epsilon_{\eta} + \epsilon_{\eta}) \leq 0.85\beta p$$

as desired.

Figure 13: Setting of Lemma 5.22

A Proofs from Section 5

Lemma 5.22. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a top edge bundle such that $x_{\mathbf{e}} \le 1/2 - \epsilon_{1/2}$. If $12\epsilon_{1/1} \le \epsilon_{1/2} \le 0.001$ then, \mathbf{e} is 2/1/1 happy with probability at least $0.005\epsilon_{1/2}^2$.

Proof. Let A,B,C be the degree partitioning of $\delta(u)$. Let $V:=\delta(v)_{-\mathbf{e}}$ (see Fig. 13). Condition u,v be trees, \mathbf{e} and C to 0, let v be the resulting measure. This happens with probability at least 0.5 and increases marginals in $A_{-\mathbf{e}},B_{-\mathbf{e}},V$ by at most $x_{\mathbf{e}}+2\epsilon_{1/1}+\epsilon_{\eta}\leq x_{\mathbf{e}}+2.1\epsilon_{1/1}$ and by tree conditioning decreases marginals by at most $2\epsilon_{\eta}$. After conditioning, we have

$$\mathbb{E}_{\nu} [A_{T}] \in x(A) - x_{\mathbf{e}(A)} + [-2\epsilon_{\eta}, x_{\mathbf{e}} + 2.1\epsilon_{1/1}] \subset [0.5, 1.5], \text{ similarly } \mathbb{E}_{\nu} [B_{T}] \subset [0.5, 1.5]$$

$$\mathbb{E}_{\nu} [V_{T}] \in x(\delta(v)) - x_{\mathbf{e}} + [-2\epsilon_{\eta}, x_{\mathbf{e}} + 2.1\epsilon_{1/1}] \subset [1.5, 2.01]$$

$$\mathbb{E}_{\nu} [B_{T} + V_{T}] \in x(B) + x(\delta(v)) - x_{\mathbf{e}} - x_{\mathbf{e}(B)} + [-2\epsilon_{\eta}, x_{\mathbf{e}} + 2.1\epsilon_{1/1}] \subset [2 + 1.8\epsilon_{1/2}, 3.01],$$

$$\mathbb{E}_{\nu} [A_{T} + B_{T}] \in x(A) + x(B) - x_{e(A)} - x_{\mathbf{e}(B)} + [-2\epsilon_{\eta}, x_{\mathbf{e}} + 2.1\epsilon_{1/1}] \subset [1.5, 2.01],$$

$$\mathbb{E}_{\nu} [A_{T} + B_{T} + V_{T}] \in x(A) + x(B) + x(\delta(v)) - x_{\mathbf{e}} - x_{e(A)} - x_{\mathbf{e}(B)} + [-2\epsilon_{\eta}, x_{\mathbf{e}} + 2.1\epsilon_{1/1}]$$

$$\subset [3 + 1.75\epsilon_{1/2}, 3.51].$$

where we used $\epsilon_{1/2} \leq 0.001$ and $12\epsilon_{1/1} < \epsilon_{1/2}$ and $x_{e(A)}, x_{\mathbf{e}(B)}, x_{e(A)} + x_{\mathbf{e}(B)} \leq x_{\mathbf{e}} \leq 1/2 - \epsilon_{1/2}$. It immediately follows from Proposition 5.1 that $\mathbb{P}_{\nu} [A_T = B_T = 1, V_T = 2]$ is at least a constant. In the rest of the proof, we do a more refined analysis. Using $A_T + B_T \geq 1, V_T \geq 1$,

$$\begin{split} \mathbb{P}_{\nu} \left[A_{T} + B_{T} + V_{T} = 4 \right] & \geq (1.75\epsilon_{1/2})e^{-1.75\epsilon_{1/2}} \geq 1.7\epsilon_{1/2}, \\ \mathbb{P}_{\nu} \left[A_{T} + B_{T} \geq 2 \right], \mathbb{P}_{\nu} \left[V_{T} \geq 2 \right] \geq 0.39, \\ \mathbb{P}_{\nu} \left[A_{T} + B_{T} \leq 2 \right], \mathbb{P}_{\nu} \left[V_{T} \leq 2 \right] \geq 0.5, \\ \mathbb{P}_{\nu} \left[A_{T} + B_{T} \leq 2 \right], \mathbb{P}_{\nu} \left[V_{T} \leq 2 \right] \geq 0.5, \\ \mathbb{P}_{\nu} \left[A_{T} \leq 1 \right] \geq 0.25, \mathbb{P}_{\nu} \left[B_{T} + V_{T} \leq 3 \right] \geq 0.33. \\ \mathbb{P}_{\nu} \left[A_{T} \geq 1 \right] \geq 0.39, \mathbb{P}_{\nu} \left[B_{T} + V_{T} \geq 3 \right] \geq 1.75\epsilon_{1/2}, \end{split} \tag{Lemma 2.22}$$

It follows by Corollary 5.5 (with $\epsilon = 0.195$, $p_m \ge 1 - 2\epsilon \ge 0.6$) that

$$\mathbb{P}_{\nu}[V_T = 2|A_T + B_T + V_T = 4] \ge 0.13.$$

Note that since $V_T \ge 1$, $A_T + B_T \ge 1$ with probability 1, we apply Corollary 5.5 to $V_T - 1$, $A_T + B_T - 1$.

Furthermore, by Lemma 5.4, \mathbb{P}_{ν} [$A_T \ge 1 | A_T + B_T + V_T = 4$] ≥ 0.128 , \mathbb{P}_{ν} [$A_T \le 1 | A_T + B_T + V_T = 4$] $\ge 0.43\epsilon_{1/2}$. The same holds for B_T . Therefore, by Corollary 5.5 (with $\epsilon = 0.055\epsilon_{1/2}$), using that $\epsilon_{1/2} < 0.001$,

$$\mathbb{P}_{\nu}\left[A_T = 1|A_T + B_T = 2, V_T = 2\right] \ge 0.05\epsilon_{1/2}.$$

Putting these together we have

$$\mathbb{P}\left[e \text{ 2-1-1 happy}\right] \geq 0.5\mathbb{P}_{\nu}\left[A_{T} = B_{T} = 1, V_{T} = 2\right]$$

$$= 0.5\mathbb{P}_{\nu}\left[A_{T} + B_{T} + V_{T} = 4\right]\mathbb{P}_{\nu}\left[V_{T} = 2|A_{T} + B_{T} + V_{T} = 4\right]$$

$$\cdot \mathbb{P}_{\nu}\left[A_{T} = 1|V_{T} = 2, A_{T} + B_{T} = 2\right]$$

$$\geq 0.5(1.7\epsilon_{1/2})(0.13)(0.05\epsilon_{1/2}) \geq 0.005\epsilon_{1/2}^{2}$$

as desired.

Lemma 5.23. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a top edge bundle such that $x_{\mathbf{e}} \ge 1/2 + \epsilon_{1/2}$. If $12\epsilon_{1/1} \le \epsilon_{1/2} \le 0.001$, then, \mathbf{e} is 2/1/1 happy with respect to u with probability at least $0.006\epsilon_{1/2}^2$.

Proof. Let A, B, C be the degree partitioning of the edges in $\delta(u)$, $V = \delta_{-\mathbf{e}}(v)$. Condition u, v be trees, $C_T = 0$ and $u \cup v$ to be a tree (in order). This happens with probability at least $\frac{1}{2} + \epsilon_{1/2} - 3\epsilon_{\eta} - 2\epsilon_{1/1} \ge 0.5$. Let ν be the resulting measure restricted to edges in A, B, V. Note that ν on edges in A, B, V is SR. This is because ν is a product of two strongly Rayleigh distribution on the following two disjoint set of edges (i) the edges between u, v and (ii) the edges in $A_{-\mathbf{e}}, B_{-\mathbf{e}}, V$.

Furthermore, observe that under ν , every set of edges in A_{-e} , B_{-e} , V increases by at most $2\epsilon_{1/1} + \epsilon_{\eta} < 0.2\epsilon_{1/2}$ (using $12\epsilon_{1/1} \le \epsilon_{1/2}$), and decreases by at most $1 - x_e + 2\epsilon_{\eta}$. Therefore,

$$\begin{split} \mathbb{E}_{\nu}\left[A_{T}\right] &\in x(A) + \left[-(1-x_{\mathbf{e}}) - 2\epsilon_{\eta}, 1 - x_{\mathbf{e}} + 0.2\epsilon_{1/2}\right] \subset [0.5, 1.5], \text{ similarly, } \mathbb{E}_{\nu}\left[B_{T}\right] \in [0.5, 1.5] \\ \mathbb{E}_{\nu}\left[V_{T}\right] &\in x(\delta(v)) - x_{\mathbf{e}} + \left[-(1-x_{\mathbf{e}}) - 2\epsilon_{\eta}, 0.2\epsilon_{1/2}\right] \subset [0.995, 1.5]. \\ \mathbb{E}_{\nu}\left[A_{T} + B_{T}\right] &\in x(A) + x(B) + 1 - x_{e(A)} - x_{\mathbf{e}(B)} + \left[-(1-x_{\mathbf{e}}) - 2\epsilon_{\eta}, 0.2\epsilon_{1/2}\right] \subset [1.995, 2.5], \\ \mathbb{E}_{\nu}\left[B_{T} + V_{T}\right] &\in x(B) + x(\delta(v)) - x_{\mathbf{e}} + \left[-(1-x_{\mathbf{e}}) - 2\epsilon_{\eta}, 1 - x_{\mathbf{e}} + 0.2\epsilon_{1/2}\right] \subset [1.99, 3 - 1.75\epsilon_{1/2}]. \\ \mathbb{E}_{\nu}\left[A_{T} + B_{T} + V_{T}\right] &\in x(A) + x(B) + x(\delta(v)) + 1 - x_{\mathbf{e}} - x_{e(A)} - x_{\mathbf{e}(B)} + \left[-(1-x_{\mathbf{e}}) - 2\epsilon_{\eta}, 0.2\epsilon_{1/2}\right] \\ &\subset [2.99, 4 - 1.75\epsilon_{1/2}]. \end{split}$$

where in the upper bound on $\mathbb{E}_{\nu}[A_T]$, $\mathbb{E}_{\nu}[B_T]$, $\mathbb{E}_{\nu}[B_T+V_T]$ we used that the marginals of edges in the bundle **e** can only increase by $1-x_{\mathbf{e}}$ (in total) when conditioning $u \cup v$ to be a tree. So,

$$\begin{split} \mathbb{P}_{\nu} \left[A_{T} + B_{T} + V_{T} = 3 \right] & \geq \epsilon_{1/2}, \\ \mathbb{P}_{\nu} \left[A_{T} + B_{T} \geq 2 \right] & \geq 0.63, \mathbb{P}_{\nu} \left[V_{T} \geq 1 \right] \geq 0.63 \\ \mathbb{P}_{\nu} \left[A_{T} + B_{T} \leq 2 \right] & \geq 0.25, \mathbb{P}_{\nu} \left[V_{T} \leq 1 \right] \geq 0.25, \\ \mathbb{P}_{\nu} \left[A_{T} + B_{T} \leq 2 \right] & \geq 0.39, \mathbb{P}_{\nu} \left[B_{T} + V_{T} \geq 2 \right] \geq 0.59 \\ \mathbb{P}_{\nu} \left[A_{T} \leq 1 \right] & \geq 0.25, \mathbb{P}_{\nu} \left[B_{T} + V_{T} \leq 2 \right] \geq 1.75 \epsilon_{1/2}, \end{split} \tag{Markov, In worst case } \mathbb{P} \left[B_{T} + V_{T} < 2 \right] = 0) \end{split}$$

It follows by Corollary 5.5 (with $\epsilon = 0.157$, $p_m = 0.68$) that

$$\mathbb{P}_{\nu}\left[A_T + B_T = 2|A_T + B_T + V_T = 3\right] \ge 0.12.$$

Note that since $A_T + B_T \ge 1$ with probability 1, we apply Corollary 5.5 to $A_T + B_T - 1$, V_T .

Furthermore, by Lemma 5.4, \mathbb{P}_{ν} [$A_T \ge 1 | A_T + B_T + V_T = 3$] $\ge 0.68\epsilon_{1/2}$ and \mathbb{P}_{ν} [$A_T \le 1 | A_T + B_T + V_T = 3$] ≥ 0.147 . By symmetry, the same holds for B_T . Therefore, by Corollary 5.5,

$$\mathbb{P}_{\nu}[A_T = 1 | A_T + B_T = 2, V_T = 1] \ge 0.09\epsilon_{1/2}.$$

where we used $\epsilon_{1/2} < 0.001$.

Finally,

$$\mathbb{P}\left[\mathbf{e} \text{ 2-1-1 happy}\right] \geq (0.09\epsilon_{1/2})0.12(\epsilon_{1/2})0.5 \geq 0.005\epsilon_{1/2}^2$$

as desired.

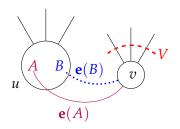

Figure 14: Setting of Lemma 5.24

Lemma 5.24. For a good half top edge bundle $\mathbf{e} = (\mathbf{u}, \mathbf{v})$, let A, B, C be the degree partitioning of $\delta(u)$, and let $V = \delta(v)_{-\mathbf{e}}$ (see Fig. 14). If $x_{\mathbf{e}(B)} \leq \epsilon_{1/2}$ and $\mathbb{P}\left[(A_{-\mathbf{e}})_T + V_T \leq 1\right] \geq 5\epsilon_{1/2}$ then \mathbf{e} is 2-1-1 good,

$$\mathbb{P}\left[\mathbf{e} \text{ 2-1-1 happy w.r.t. } u\right] \geq 0.005\epsilon_{1/2}^2$$

Proof. The proof is similar to Lemma 5.23. We condition u, v to be trees, $C_T = 0$, $u \cup v$ to be a tree. Let v be the resulting SR measure on edges in A, B, V. The main difference is since $x_{\mathbf{e}} \not\geq 1/2 + \epsilon_{1/2}$ we use the lemma's assumptions to lower bound $\mathbb{P}_v \left[A_T + B_T + V_T = 3 \right]$, $\mathbb{P}_v \left[A_T + V_T \leq 2 \right]$, $\mathbb{P}_v \left[B_T + V_T \leq 2 \right]$. First, since \mathbf{e} is 2-2 good, by Lemma 5.15 and negative association,

$$\mathbb{P}_{\nu} \left[(\delta(u)_{-\mathbf{e}})_T + V_T \le 2 \right] \ge \mathbb{P} \left[(\delta(u)_{-\mathbf{e}})_T + V_T \le 2 \right] - \mathbb{P} \left[C_T = 0 \right] \ge 0.4 \epsilon_{1/2} - 2\epsilon_{1/1} - \epsilon_{\eta} \ge 0.22 \epsilon_{1/2},$$

where we used $\epsilon_{1/1} < 12\epsilon_{1/2}$. Letting $p_i = \mathbb{P}\left[(\delta(u)_{-\mathbf{e}})_T + V_T = i\right]$, we therefore have $p_{\leq 2} \geq 0.22\epsilon_{1/2}$. In addition, by Lemma 2.21, $p_3 \geq 1/4$. If $p_2 < 0.2\epsilon_{1/2}$, then from $p_2/p_3 \leq 0.8\epsilon_{1/2}$, we could use log-concavity to derive a contradiction to $p_{\leq 2} \geq 0.22\epsilon_{1/2}$ (analogously to what's done in the proof of Lemma 2.18). Therefore, we must have

$$\mathbb{P}_{\nu}[A_T + B_T + V_T = 3] = \mathbb{P}_{\nu}[(\delta(u)_{-\mathbf{e}})_T + V_T = 2] \ge 0.2\epsilon_{1/2}.$$

Next, notice since $\mathbb{P}\left[u,v,u\cup v \text{ trees},C_T=0\right] \geq 0.49$, by the lemma's assumption, $\mathbb{P}_{\nu}\left[\mathbf{e}(B)\right] \leq 2.01\epsilon_{1/2}$. Therefore,

$$\mathbb{E}_{\nu} \left[B_T + V_T \right] \le x(V) + x(B) + 1.01\epsilon_{1/2} + 2\epsilon_{1/1} + \epsilon_{\eta} \le 2.51.$$

So, by Markov, $\mathbb{P}_{\nu}[B_T + V_T \leq 2] \geq 0.15$. Finally, by negative association,

$$\mathbb{P}_{\nu}\left[A_T + V_T \leq 2\right] \geq \mathbb{P}_{\nu}\left[(A_{-\mathbf{e}})_T + V_T \leq 1\right] \geq \mathbb{P}\left[(A_{-\mathbf{e}})_T + V_T \leq 1\right] - \mathbb{P}\left[C_T = 0\right] \geq 4.8\epsilon_{1/2}$$

where we used the lemma's assumption.

Now, following the same line of arguments as in Lemma 5.23, we have $\mathbb{P}_{\nu}\left[A_T+B_T=2|A_T+B_T+V_T=3\right] \geq 0.12$. Also, $\mathbb{P}_{\nu}\left[A_T\geq 1|A-T+B_T+V_T=3\right] \geq 3.02$, which implies $\mathbb{P}_{\nu}\left[A_T=1|A_T+B_T=2,V_T=1\right] \geq 0.42\epsilon$. This implies

$$\mathbb{P}\left[\mathbf{e} \text{ 2-1-1 happy}\right] \ge (0.42\epsilon_{1/2})0.12(0.2\epsilon_{1/2})0.498 \ge 0.005\epsilon_{1/2}^2$$

as desired.

Lemma 5.25. Let $\mathbf{e} = (\mathbf{v}, \mathbf{u})$ and $\mathbf{f} = (\mathbf{v}, \mathbf{w})$ be good half top edge bundles and let A, B, C be the degree partitioning of $\delta(v)$ such that $x_{\mathbf{e}(B)}, x_{\mathbf{f}(B)} \leq \epsilon_{1/2}$. Then, one of \mathbf{e}, \mathbf{f} is 2-1-1 happy with probability at least $0.005\epsilon_{1/2}^2$.

Proof. Let $U = \delta(u)_{-e}$. By Lemma 2.27, we can assume, without loss of generality, that

$$\mathbb{E}\left[U_T|\mathbf{f} \notin T, u, v, w \text{ tree}\right] \le x(U_T) + 0.405 + 3\epsilon_n. \tag{50}$$

On the other hand,

$$\mathbb{E}\left[(A_{-\mathbf{e}-\mathbf{f}})_T\right] \ge \mathbb{E}\left[(A_{-\mathbf{e}-\mathbf{f}})_T\middle|\mathbf{f} \notin T, u, v, w \text{ tree}\right] \mathbb{P}\left[\mathbf{f} \notin T, u, v, w, \text{ tree}\right]$$

$$\ge \mathbb{E}\left[(A_{-\mathbf{e}-\mathbf{f}})_T\middle|\mathbf{f} \notin T, u, v, w \text{ tree}\right] 0.49$$

So,

$$\mathbb{E}\left[(A_{-\mathbf{e}-\mathbf{f}})_T | \mathbf{f} \notin T, u, v, w, \text{ tree}\right] \le \frac{1}{0.49} x(A_{-\mathbf{e}-\mathbf{f}}) \le \frac{1}{0.49} (4\epsilon_{1/2} + \epsilon_{\eta}) \le 8.2\epsilon_{1/2}. \tag{51}$$

Combining (50) and (51), we get $\mathbb{E}[U_T + (A_{-\mathbf{e}})|\mathbf{f} \notin T, u, v, w \text{ tree}] \leq 1.91$ where we used $\epsilon_{1/2} \leq 0.001$. Therefore, using Lemma 2.21, we get

$$\mathbb{P}[U_T + (A_{-\mathbf{e}})_T \le 1] \ge 0.49 \mathbb{P}[U_T + (A_{-\mathbf{e}})_T \le 1 | \mathbf{f} \notin T, u, v, w \text{ tree}] \ge 0.01,$$

Since $\epsilon_{1/2} \le 0.001$, by Lemma 5.24, **e** is 2-1-1 good.

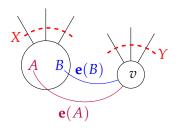

Figure 15: Setting of Lemma 5.26.

Lemma 5.26. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v})$ be a good half edge bundle and let A, B, C be the degree partitioning of $\delta(u)$ (see Fig. 15). If $12\epsilon_{1/1} \le \epsilon_{1/2} \le 0.001$ and $x_{\mathbf{e}(A)}, x_{\mathbf{e}(B)} \ge \epsilon_{1/2}$, then

$$\mathbb{P}\left[\mathbf{e} \text{ 2-1-1 happy w.r.t } u\right] \geq 0.02\epsilon_{1/2}^2.$$

Proof. Condition C_T to be zero, u, v and $u \cup v$ be trees. This happens with probability at least 0.49. Let v be the resulting measure. Let $X = A_{-\mathbf{e}} \cup B_{-\mathbf{e}}, Y = \delta(v)_{-\mathbf{e}}$ Since \mathbf{e} is 2/2 good by Lemma 5.15 and stochastic dominance,

$$\mathbb{P}_{\nu}\left[X_T + Y_T \leq 2\right] \geq \mathbb{P}\left[\left(\delta(u)_{-\mathbf{e}}\right)_T + Y_T \leq 2\right] - \mathbb{P}\left[C_T = 0\right] \geq 0.4\epsilon_{1/2} - 2\epsilon_{1/1} - \epsilon_{\eta} \geq 0.22\epsilon_{1/2}$$

where we used $\epsilon_{1/1} < 12\epsilon_{1/2}$. It follows by log-concavity of $X_T + Y_T$ that $\mathbb{P}_{\nu}[X_T + Y_T = 2] \ge 0.2\epsilon_{1/2}$. Now,

$$\mathbb{E}_{\nu}\left[X_{T}\right], \mathbb{E}_{\nu}\left[Y_{T}\right] \in \left[1 - 3\epsilon_{1/1}, 1.5 + \epsilon_{1/2} + 2\epsilon_{1/1} + 3\epsilon_{\eta}\right] \subset \left[0.995, 1.51\right]$$

So,

$$\mathbb{P}_{\nu}[X_T \ge 1]$$
, $\mathbb{P}_{\nu}[Y_T \ge 1] \ge 0.63$, (Lemma 2.22) $\mathbb{P}_{\nu}[X_T \le 1]$, $\mathbb{P}_{\nu}[Y_T \le 1] \ge 0.245$. (Markov)

Therefore, by Corollary 5.5 $\mathbb{P}_{\nu}[X_T = 1 | X_T + Y_T = 2] \ge 0.119$.

$$\mathbb{P}_{\nu}[X_T = Y_T = 1] \ge (0.2\epsilon_{1/2})0.119 \ge 0.023\epsilon_{1/2}$$

Let \mathcal{E} be the event $\{X_T = Y_T = 1 | \nu\}$. Note that in ν we always choose exactly 1 edge from the **e** bundle and that is independent of edges in X, Y, in particular the above event. Therefore, we can correct the parity of A, B by choosing from e_A or e_B . It follows that

$$\mathbb{P}\left[\mathbf{e} \ 2/1/1 \text{ happy w.r.t } u\right] \geq \mathbb{P}_{\nu}\left[\mathcal{E}\right] (1.99\epsilon_{1/2}) 0.49 \geq 0.02\epsilon_{1/2}^2$$

where we used that $\mathbb{E}_{\nu}\left[\mathbf{e}(A)_{T}\right] \geq 1.99\epsilon_{1/2}$, and the same fact for $\mathbf{e}(B)_{T}$. To see why this latter fact is true, observe that conditioned on u,v trees, we always sample at most one edge between u,v. Therefore, since under ν we choose exactly one edge between u,v, the probability of choosing from $\mathbf{e}(A)$ (and similarly choosing from $\mathbf{e}(B)$) is at least

$$\frac{\mathbb{E}\left[\mathbf{e}(A)_T|u,v \text{ trees}, C_T=0\right]}{\mathbb{P}\left[\mathbf{e}|u,v \text{ trees}, C_T=0\right]} \geq \frac{x_{\mathbf{e}(A)}-2\epsilon_{\eta}}{x_{\mathbf{e}}+3\epsilon_{1/1}} \geq \frac{\epsilon_{1/2}-2\epsilon_{\eta}}{1/2+1.3\epsilon_{1/2}} \geq 1.99\epsilon_{1/2}$$

as desired.

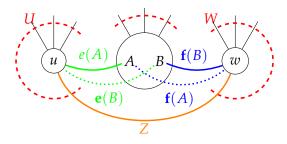

Figure 16: Setting of Lemma 5.27. We assume that the dotted green/blue edges are at most $\epsilon_{1/2}$. Note that edges of C are not shown.

Lemma 5.27. Let $\mathbf{e} = (\mathbf{u}, \mathbf{v}), \mathbf{f} = (\mathbf{v}, \mathbf{w})$ be two good top half edge bundles and let A, B, C be degree partitioning of $\delta(v)$ such that $x_{\mathbf{e}(B)}, x_{\mathbf{f}(A)} \leq \epsilon_{1/2}$. If \mathbf{e} , \mathbf{f} are not 2-1-1 good with respect to v, and $12\epsilon_{1/1} \leq \epsilon_{1/2} \leq 0.0002$, then \mathbf{e} , \mathbf{f} are 2-2-2 happy with probability at least 0.01.

Proof. First, observe that by Lemma 5.24 if $\mathbb{P}\left[U_T + (A_{-\mathbf{e}})_T \le 1\right] \ge 0.25\epsilon$, where $\epsilon \ge 20\epsilon_{1/2}$ is a constant that we fix later, then \mathbf{e} is 2/1/1 good and we are done. So, assume, $\mathbb{P}\left[U_T + (A_{-\mathbf{e}})_T \ge 2\right] \ge 1 - 0.25\epsilon$. Furthermore, let $q = \mathbb{P}\left[U_T + (A_{-\mathbf{e}})_T \ge 3\right]$. Since $x(U) + x(A_{-\mathbf{e}}) \le 2 + 3\epsilon_{1/2} + 2\epsilon_{1/1} + 3\epsilon_{\eta} \le 2 + 3.2\epsilon_{1/2}$ (where we used $x_{\mathbf{e}(A)} \ge x_{\mathbf{e}} - x_{\mathbf{e}(B)} - x_C \ge 1/2 - 2\epsilon_{1/2} - 2\epsilon_{1/1} - \epsilon_{\eta}$ and where we used $12\epsilon_{1/1} \le \epsilon_{1/2}$),

$$2(1 - q - 0.25\epsilon) + 3q \le 2 + 3.2\epsilon_{1/2}.$$

This implies that $q \le 0.5\epsilon + 3.2\epsilon_{1/2} \le 0.75\epsilon$ (for $\epsilon \ge 13\epsilon_{1/2}$). Therefore,

$$\mathbb{P}[U_T + (A_{-\mathbf{e}})_T = 2], \mathbb{P}[W_T + (B_{-\mathbf{f}})_T = 2] \ge 1 - \epsilon$$
(52)

where the second inequality follows by a similar argument.

Claim A.1. Let $Z = \delta(u) \cap \delta(w)$. If $\epsilon < 1/15$, then either $\mathbb{E}[Z|u,v,w \text{ tree}] \leq 3\epsilon$ or $\mathbb{E}[Z|u,v,w \text{ tree}] \geq (1-3\epsilon)$.

Proof. For the whole proof we work with μ conditioned on u, v, w are trees. Let $z = \mathbb{E}[Z]$. Let $D = U \cup W \cup A_{-\mathbf{e}} \cup B_{-\mathbf{f}} \setminus Z$. Note that $D_T + 2Z_T = U_T \cup W_T \cup (A_{-\mathbf{e}})_T \cup (B_{-\mathbf{f}})_T$. By Eq. (52) and a union bound $\mathbb{P}[D_T + 2Z_T = 4] \ge 1 - 2\epsilon - 3\epsilon_n$. Therefore,

$$2.1\epsilon \geq 2\epsilon + 3\epsilon_{\eta} \geq \mathbb{P}\left[D_T + 2Z_T \neq 4\right] \geq \mathbb{P}\left[D_T = 3\right] \geq \sqrt{\mathbb{P}\left[D_T = 2\right]\mathbb{P}\left[D_T = 4\right]}$$

where the last inequality follows by log-concavity. On the other hand,

$$z = \mathbb{P}[Z = 1] \le \mathbb{P}[D_T = 2, Z = 1] + \mathbb{P}[D_T + 2Z_T \ne 4] \le \mathbb{P}[D_T = 2] + 2.1\epsilon,$$

 $1 - z = \mathbb{P}[Z = 0] \le \mathbb{P}[D_T = 4, Z = 0] + \mathbb{P}[D_T + 2Z_T \ne 4] \le \mathbb{P}[D_T = 4] + 2.1\epsilon$

Putting everything together,

$$(2.1\epsilon)^2 \ge (z - 2.1\epsilon)(1 - z - 2.1\epsilon) = z(1 - z) - 2.1\epsilon + 2.1\epsilon^2.$$

Therefore, using $\epsilon \le 1/15$, we get that either $z \le 3\epsilon$ or $z \ge 1 - 3\epsilon$.

So, for the rest of proof we assume $\mathbb{E}\left[Z_T|u,v,w \text{ trees}\right] < 3\epsilon$. A similar proof shows \mathbf{e} , \mathbf{f} are 2-2-2 good when $\mathbb{E}\left[Z_T|u,v,w \text{ trees}\right] > 1 - 3\epsilon$. We run the following conditionings in order: u,v,w trees, $Z_T = 0$, $C_T = 0$, $\mathbf{e}(B)$, $\mathbf{f} \notin T$, $\mathbf{e}(A) \in T$. Note that $\mathbf{e}(A) \in T$ is equivalent to $u \cup v$ be a tree. Call this event \mathcal{E} (i.e., the event that all things we conditioned on happen). First, notice

$$\mathbb{P}\left[\mathcal{E}\right] \ge (1 - 3\epsilon_{\eta})(1 - 3\epsilon - 2\epsilon_{1/1} - \epsilon_{\eta} - \epsilon_{1/2} - (1/2 + \epsilon_{1/2}))(1/2 - 3\epsilon_{1/2}) \ge 0.22 \ge 1/5 \quad (53)$$

Moreover, since all of these conditionings correspond to upward/downward events, $\mu | \mathcal{E}$ is strongly Rayleigh. The main statement we will show is that

$$\mathbb{P}\left[\mathbf{e},\mathbf{f} \text{ 2-2-2 happy}|\mathcal{E}\right] \geq \mathbb{P}\left[U_T = (A_{-\mathbf{e}})_T = 1, (B_{-\mathbf{f}})_T = 0, W_T = 2|\mathcal{E}\right] = \Omega(1).$$

The main insight of the proof is that Eq. (52) holds (up to a larger constant of ϵ), even after conditioning \mathcal{E} , $B_{-\mathbf{f}} = 0$, $A_{-\mathbf{e}} = 1$; so, we can bound the preceding event by just a union bound. The main non-trivial statement is to argue that the expectations of $B_{-\mathbf{f}}$ and $A_{-\mathbf{e}}$ do not change so much under \mathcal{E} .

Combining (52) and (53),

$$\mathbb{P}[U_T + (A_{-e})_T = 2|\mathcal{E}], \mathbb{P}[W_T + (B_{-f})_T = 2|\mathcal{E}] \ge 1 - 5\epsilon.$$
 (54)

We claim that

$$\mathbb{E}\left[B_T|\mathcal{E}\right] = \mathbb{E}\left[(B_{-\mathbf{f}})_T|\mathcal{E}\right] \le x(B_{-\mathbf{f}}) + 3\epsilon_{\eta} + 3\epsilon_{1/1} + \epsilon_{1/2} + 35\epsilon \le 0.66 \tag{55}$$

using $\epsilon_{1/2} < 0.0002$ and $\epsilon = 20\epsilon_{1/2}$. To see this, observe that after each conditioning in $\mathcal E$ either all marginals increase or all decrease. Furthermore, the events $C_T = 0$, $Z_T = 0$, $\mathbf e(B)_T = 0$ can increase marginals by at most $3\epsilon_\eta + 3\epsilon_{1/1} + \epsilon_{1/2}$; the only other event that can increase $B_{-\mathbf f}$ is $\mathbf f \notin T$. Now we know $\mathbb P\left[B_{-\mathbf f}\right]_T + W_T = 2|\mathcal E| \ge 1 - 5\epsilon$ before and after conditioning $\mathbf f \notin T$. Therefore, by Corollary 2.19, $2 - 10\epsilon \le \mathbb E\left[B_{-\mathbf f}\right]_T + W_T \le 2 + 25\epsilon$. But if $\mathbb E\left[B_{-\mathbf f}\right]_T$ increased by more than 35ϵ , then either before conditioning $\mathbf f \notin T$, $\mathbb E\left[(B_{-\mathbf f}) + W_T\right] < 2 - 10\epsilon$ or afterwards it is more than $2 + 25\epsilon$, which is a contradiction, and completes the proof of (55). A similar argument shows that $\mathbb E\left[(A_{-\mathbf e})_T|\mathcal E\right] \le 0.66$.

We also claim that

$$\mathbb{E}\left[(A_{-e})_T|\mathcal{E}\right] \ge x(A_{-e}) - 3\epsilon_{\eta} - 35\epsilon \ge 0.33.$$

As above, everything conditioned on in \mathcal{E} increases $\mathbb{E}[(A_{-e})_T]$ except for possibly $\mathbf{e}(A) \in T$. As above, we know that $\mathbb{P}[U_T + (A_{-e})_T = 2|\mathcal{E}] \geq 1 - 5\epsilon$ before and after $\mathbf{e}(A) \notin T$. So again applying Corollary 2.19, we see that it can't decrease by more than 35ϵ .

It follows that

$$0.33 \le \mathbb{E}\left[(A_{-\mathbf{e}})_T | \mathcal{E} \right] \le \mathbb{E}\left[(A_{-\mathbf{e}})_T | \mathcal{E}, (B_{-\mathbf{f}})_T = 0 \right] \le 0.66 + 0.66 \le 1.32.$$

So, by Lemma 2.21 and Theorem 2.15, $\mathbb{P}\left[(A_{-\mathbf{e}})_T = 1 | \mathcal{E}, (B_{-f})_T = 0\right] \ge 0.33e^{-.33} \ge 0.237$. Therefore, by Lemma 2.21

$$\mathbb{P}\left[\mathcal{E}, (A_{-\mathbf{e}})_T = 1, (B_{-\mathbf{f}})_T = 0\right] \ge (0.22)(0.39)(0.23) \ge 0.019.$$

Therefore, by (54)

$$\mathbb{P}\left[U_T = 1 | \mathcal{E}_{\tau}(A_{-\mathbf{e}})_T = 1, (B_{-\mathbf{f}})_T = 0\right], \mathbb{P}\left[W_T = 2 | \mathcal{E}_{\tau}(A_{-\mathbf{e}})_T = 1, (B_{-\mathbf{f}})_T = 0\right] \ge 1 - 5\epsilon/0.019$$

Finally, by union bound

$$\mathbb{P}\left[U_T = 1, W_T = 2 | \mathcal{E}_{t}(A_{-e})_T = 1, (B_{-e})_T = 0\right] > 1 - \epsilon/0.009$$

Using $\epsilon = 20\epsilon_{1/2}$ and $\epsilon_{1/2} \leq 0.0002$ this means both of the above events happens, so **e**, **f** are 2-2-2-happy with probability $0.019(1 - \epsilon/0.009) > 0.01$ as desired.
